Abstract. We prove exponential rates of convergence of $hp$-dG interior penalty (IP) methods for second-order elliptic problems with mixed boundary conditions in polyhedra which are based on axiparallel, $\sigma$-geometric anisotropic meshes of mapped hexahedra and anisotropic polynomial degree distributions of $\mu$-bounded variation. Compared to homogeneous Dirichlet boundary conditions in [10, 11], for problems with mixed Dirichlet-Neumann boundary conditions, we establish exponential convergence for a nonconforming dG interpolant consisting of elementwise $L^2$ projections onto elemental polynomial spaces with possibly anisotropic polynomial degrees, and for solutions which belong to a larger analytic class than the solutions considered in [11].

New arguments are introduced for exponential convergence of the dG consistency errors in elements abutting on Neumann edges due to the appearance of non-homogeneous, weighted norms in the analytic regularity at corners and edges. The non-homogeneous norms entail a reformulation of dG flux terms near Neumann edges, and modification of the stability and quasi-optimality proofs, and the definition of the anisotropic interpolation operators. The exponential convergence results for the piecewise $L^2$ projection generalizes [10, 11] also in the Dirichlet case.

1. Introduction

Consider an open, bounded polyhedron $\Omega \subset \mathbb{R}^3$ with Lipschitz boundary $\Gamma = \partial \Omega$ that consists of a finite union of plane faces $\Gamma_\iota$ indexed by $\iota \in J$. The sets $\Gamma_\iota$ are assumed to be bounded, plane polygons whose sides form the (open) edges of $\Omega$. The set $\{\Gamma_\iota\}_{\iota \in J}$ is partitioned into two sets $J_D$ and $J_N$ of Dirichlet and of Neumann faces, respectively, i.e., $J = J_D \cup J_N$, with disjoint union. Then we consider the diffusion equation

$$\begin{align*}
-\Delta u &= f \quad \text{in } \Omega, \\
\gamma_0(u) &= 0 \quad \text{on } \Gamma_\iota \subset \partial \Omega, \quad \iota \in J_D, \\
\gamma_1(u) &= 0 \quad \text{on } \Gamma_\iota \subset \partial \Omega, \quad \iota \in J_N,
\end{align*}$$

(1.1-1.3)

where the operators $\gamma_0$ and $\gamma_1$ denote the trace and (co)normal derivative operators, respectively. With the Sobolev space $V := H^1_D(\Omega) := \{v \in H^1(\Omega) : v|_{\Gamma_\iota} = 0, \ \iota \in J_D\}$ and the continuous bilinear form $a(u, v) := \int_\Omega \nabla u \cdot \nabla v \, d\mathbf{x}$, the variational form of problem (1.1)-(1.3) is to find $u \in H^1_D(\Omega)$ such that

$$a(u, v) = \int_\Omega fv \, d\mathbf{x} \quad \forall v \in H^1_D(\Omega).$$

(1.4)

For every $f \in V^* = H^1_D(\Omega)^*$, the dual space of $V$, problem (1.4) admits a weak solution $u \in H^1_D(\Omega)$. The solution is unique if $J_D \neq \emptyset$, and unique up to constants if $J_D = \emptyset$ (in which case we also require the compatibility condition $\langle f, 1 \rangle_{V^* \times V} = 0$).

This paper is a continuation of our work [10, 11] on $hp$-version discontinuous Galerkin (dG) finite element methods (FEM) for second-order elliptic boundary-value problems in polyhedral domains $\Omega \subset \mathbb{R}^3$. In [10], we showed the well-posedness, stability and quasi-optimality of $hp$-version interior penalty (IP) discontinuous Galerkin discretizations of (1.1) in the pure Dirichlet case when $J = J_D, J_N = \emptyset$, and the homogeneous essential boundary conditions (1.2) are posed.

2010 Mathematics Subject Classification. 65N30.

Key words and phrases. $hp$-dGFEM, second-order elliptic problems in 3D polyhedra, mixed Dirichlet-Neumann boundary conditions, exponential convergence.

on all of $\partial \Omega$. In [11], we then used these results to prove exponential rates of convergence in the number of degrees of freedom, on appropriate combinations of $\sigma$-geometric meshes and $\sigma$-linearly increasing anisotropic elemental polynomial degrees; see also [14] for related work on linear elasticity.

In this work, we consider the case $\mathcal{J}_N \neq \emptyset$. The case $\mathcal{J}_N = \emptyset$ is the pure Dirichlet case where exponential convergence was established in [10, 11]. The $hp$-error analysis in the present paper is along the lines of [10, 11], however, there are some significant differences: as shown in [3], the solutions of mixed Dirichlet-Neumann or pure Neumann problems for second order, elliptic boundary value problems in polyhedral domains with piecewise analytic data belong to analytic classes specified in terms of countably normed Sobolev spaces. In elements in the vicinity of $\Gamma_\iota$, for $\iota \in \mathcal{J}_D$, the analytic classes coincide with those for the Dirichlet case, and accordingly, exponential convergence would follow as in [11]. In the present paper, we provide an alternative proof also in the Dirichlet case, constructing an $hp$-interpolant from elementwise $L^2$-projections. The exponential convergence proofs in this work will focus on stability and exponential convergence bounds in elements in the vicinity of $\Gamma_\iota, \iota \in \mathcal{J}_N$. Here, new technical difficulties (as compared to [11]) arise, due to the solutions belonging to countably normed Sobolev spaces with nonhomogeneous weights $N^m_B(\Omega)$ introduced in [3]. In the case of homogeneous Dirichlet conditions (i.e., when $\mathcal{J}_N = \emptyset$), these spaces coincide with the (smaller) spaces $M_B^m(\Omega)$ for which we proved exponential convergence in [10, 11]. When $\mathcal{J}_N \neq \emptyset$, however, we have the strict inclusion $N^m_B(\Omega) \supset M_B^m(\Omega)$, due to the different structure of the weights near Neumann edges, i.e., edges at the intersection of two faces $\Gamma_\iota, \iota \in \mathcal{J}_N$. Compared to [10, 11], the different structure of the weights entails essential modifications in the definition of the anisotropic $hp$-interpolation operators, as well as in the error bounds in elements containing Neumann faces. Compared to the results of [10, 11], we present here an $hp$-dG discretization for (1.1)–(1.3) with $\mathcal{J}_N \neq \emptyset$. On axiparallel hexahedral meshes and for linear anisotropic polynomial degree distributions, and for isotropic diffusion coefficients, we establish exponential convergence. Specifically, we show that the $hp$-dG approximations are well-defined, satisfy the Galerkin orthogonality property and, hence, the dG energy error can be bounded with respect to a suitable discontinuous elemental polynomial interpolation operator. We generalize the result in [11] (for the case $\mathcal{J}_N = \emptyset$), and prove that $hp$-dGFEM achieve exponential convergence, i.e., asymptotic convergence rate bounds of the form $C \exp(-b\sqrt{N})$, where $N$ is the number of degrees of freedom, and where $b, C > 0$ are independent of $N$.

The outline of the article is as follows: In Section 2, we recapitulate regularity results in countably normed weighted Sobolev spaces for the solution of (1.1)–(1.3) from [3], extending the pioneering work [2] in two dimensions to the three-dimensional case. In Section 3, we define $hp$-dG finite element spaces on $\sigma$-geometric meshes of mapped hexahedral elements with possibly anisotropic polynomial degree distributions. In Section 4, we extend the stability and quasi-optimality results of [10] to the mixed boundary conditions considered here. Particular attention is being paid to the analysis of consistency errors in elements abutting at “Neumann-edges”, being edges where two faces with homogeneous Neumann boundary conditions meet. In Section 5, we present exponential convergence bounds for the consistency terms arising in the dG-stability analysis, and state our exponential convergence result (Theorem 5.6). Sections 6–7.6 are devoted to the proof of this result. Although we use ideas and notation from [10, 11], the proof of exponential convergence in the present paper is self-contained, and the results in several respects stronger than the analysis in [11]: exponential convergence is shown for larger classes of solutions, and for an (quasi)interpolant which requires merely $L^2$-regularity of the solution, thereby generalizing the analysis in [11]. This is purchased at the expense of additional powers of the maximal polynomial degree (as compared to [11]) appearing in the consistency error bounds; these are subsequently absorbed into the exponentially small terms.

The notation employed throughout this paper is consistent with [10, 11]. In particular, we shall frequently use the function

$$\Psi_{q,r} = \frac{\Gamma(q + 1 - r)}{\Gamma(q + 1 + r)}, \quad 0 \leq r \leq q, \ q, r \in \mathbb{N},$$ (1.5)
where $\Gamma$ is the Gamma function satisfying $\Gamma(m + 1) = m!$, for any $m \in \mathbb{N}$. Moreover, we shall use the notations "$\lesssim$" or "$\gtrsim$" to mean an inequality or an equivalence containing generic positive multiplicative constants which are independent of the local mesh sizes, polynomial degrees, and regularity parameters, as well as of the geometric refinement level, but which may depend on the geometric refinement ratio $\sigma$ and on the linear polynomial degree slope $s$.

2. Regularity

To establish exponential convergence of $hp$-DGF methods, it is necessary to specify the precise regularity of solutions of (1.1)–(1.3) in countably normed weighted Sobolev spaces. To do so, we follow [3], based on the notations already introduced in [10, 11].

2.1. Subdomains and Weights. We denote by $\mathcal{C}$ the set of corners $c$, and by $\mathcal{E}$ the set of open edges $e$ of $\Omega$. The singular set of $\Omega$ is then given by

$$\mathcal{S} = \bigcup_{c \in \mathcal{C}} e \cup \bigcup_{e \in \mathcal{E}} e \subset \Gamma.$$  

For $c \in \mathcal{C}$, $e \in \mathcal{E}$, and $x \in \Omega$, we define the following distance functions:

$$r_c(x) = \text{dist}(x, c), \quad r_e(x) = \text{dist}(x, e), \quad \rho_{ce}(x) = r_e(x)/r_c(x).$$  

We assume the vertices of $\Omega$ to be separated:

$$\exists \varepsilon(\Omega) > 0 : \bigcap_{c \in \mathcal{C}} B_{\varepsilon}(c) = \emptyset,$$  

where $B_{\varepsilon}(c)$ denotes the open ball in $\mathbb{R}^3$ with center $c$ and radius $\varepsilon$. For each corner $c \in \mathcal{C}$, $\mathcal{E}_c = \{ e \in \mathcal{E} : e \cap c \neq \emptyset \}$ denotes the set of all edges of $\Omega$ which meet at $c$. Similarly, for any $e \in \mathcal{E}$, the set of corners of $e$ is given by $\mathcal{C}_e \equiv \partial e = \{ c \in \mathcal{C} : e \cap c \neq \emptyset \}$. Then, for $c \in \mathcal{C}$, $e \in \mathcal{E}$ and $e_c \in \mathcal{E}_c$, we define the neighborhoods

$$\omega_c = \{ x \in \Omega : r_c(x) < \varepsilon \land \rho_{ce}(x) > \varepsilon \ \forall e \in \mathcal{E}_c \},$$

$$\omega_e = \{ x \in \Omega : r_e(x) < \varepsilon \land r_e(x) > \varepsilon \ \forall c \in \mathcal{C}_e \},$$

$$\omega_{c e} = \{ x \in \Omega : r_c(x) < \varepsilon \land \rho_{ce}(x) < \varepsilon \}.$$  

Possibly by reducing $\varepsilon$ in (2.3), we may partition the domain $\Omega$ into four disjoint parts,

$$\bar{\Omega} = \Omega_0 \cup \Omega_C \cup \Omega_E \cup \Omega_{CE},$$  

where

$$\Omega_C = \bigcup_{e \in \mathcal{E}_c} \omega_e, \quad \Omega_E = \bigcup_{e \in \mathcal{E}} \omega_e, \quad \Omega_{CE} = \bigcup_{e \in \mathcal{E}_c \in \mathcal{E}_e} \omega_{c e}.$$  

We shall refer to the subdomains $\Omega_C$, $\Omega_E$ and $\Omega_{CE}$ as corner, edge and corner-edge neighborhoods of $\Omega$, respectively, and the remaining interior part of the domain $\Omega$ is defined by $\Omega_0 := \Omega \setminus \overline{\Omega_C \cup \Omega_E \cup \Omega_{CE}}$.

In the sequel, it will be useful to refine the partition in (2.6) by introducing the following subsets of $\mathcal{C}$ and $\mathcal{E}$, respectively:

$$\mathcal{C}_D := \{ c \in \mathcal{C} : \exists s \in \mathcal{J}_D \text{ with } c \cap \Gamma_s \neq \emptyset \},$$

$$\mathcal{E}_D := \{ e \in \mathcal{E} : \exists s \in \mathcal{J}_D \text{ with } e \cap \Gamma_s \neq \emptyset \},$$

$$\mathcal{E}_N := \mathcal{E} \setminus \mathcal{E}_D.$$  

Corners in $\mathcal{C}_D$ and edges in $\mathcal{E}_D$ abut at least one Dirichlet face $\Gamma_s$ for $s \in \mathcal{J}_D$. Note that we possibly have $\mathcal{E}_N = \emptyset$. Hence, the edge neighborhoods in (2.6) can be further partitioned into:

$$\Omega_E = \Omega_{E_D} \cup \Omega_{E_N},$$  

where, as in (2.6), we let $\Omega_{E_D} = \bigcup_{e \in \mathcal{E}_D} \omega_e$, and $\Omega_{E_N} = \bigcup_{e \in \mathcal{E}_N} \omega_e$. 
2.2. Weighted Sobolev Spaces. To each \( c \in C \) and \( e \in E \) we associate a corner and an edge exponent \( \beta_c, \beta_e \in \mathbb{R} \), respectively. We collect these quantities in the multi-exponent
\[
\beta = \{ \beta_c : c \in C \} \cup \{ \beta_e : e \in E \} \in \mathbb{R}^{[C]+[E]}.
\]
Inequalities of the form \( \beta < 1 \) and expressions like \( \beta \pm s \), where \( s \in \mathbb{R} \), are to be understood componentwise. For example, \( \beta + s = \{ \beta_c + s : c \in C \} \cup \{ \beta_e + s : e \in E \} \). We shall often use the notation
\[
b_{c} = -1 - \beta_{c}, \quad c \in C, \quad b_{e} = -1 - \beta_{e} \quad e \in E.
\]

At the heart of the exponential convergence analysis of \( hp \)-approximations in three dimensions is the analytic regularity of the solution \( u \) of (1.1)–(1.2) near the set of edges \( E \) of \( \Omega \). In order to describe it, we recall from [10], for corners \( c \in C \) and edges \( e \in E \), the local coordinate systems in \( \omega_{c} \) and \( \omega_{ce} \) which are chosen such that \( e \) corresponds to the direction \((0, 0, 1)\). Then, we denote quantities that are transversal to \( e \) by \((\cdot)_{e}^{-} \), and quantities parallel to \( e \) by \((\cdot)_{e}^{+} \). In particular, if \( \alpha = (\alpha_{e}^{-}, \alpha_{e}^{+}) \) with \( \alpha_{e}^{-} = (\alpha_{1}, \alpha_{2}) \) and \( \alpha_{e}^{+} = \alpha_{3} \) is a multi-index corresponding to the three local coordinate directions in a subdomain \( \omega_{c} \) or \( \omega_{ce} \), then the operator \( \mathbf{D}^{\alpha} \) denotes the partial derivative in these local coordinate directions. Likewise notation shall be employed below in anisotropic quantities related to a face. Furthermore, we will write \( |\alpha_{e}^{+}| = \alpha_{1} + \alpha_{2} \), and \( |\alpha| = |\alpha_{e}^{+}| + \alpha_{3} \).

The solution \( u \) of (1.1)–(1.3) belongs to a scale \( N_{h}^{m}(\Omega) \) of countably normed spaces which are, in the case \( J_{\mathcal{F}} \neq \emptyset \) under consideration here, strictly larger than the scale \( M_{h}^{m}(\Omega) \) of spaces considered in [10, 11] for the pure Dirichlet case, i.e., for \( J = J_{D} \), so that the exponential convergence results proved in this paper generalize those in [10, 11]. We define the semi-norm
\[
\|u\|_{N_{h}^{m}(\Omega; \mathcal{C}_{D}, \mathcal{E}_{D})} := \left\{ \begin{array}{ll}
\sum_{e \in \mathcal{C}_{D}} \| \mathbf{D}^{\alpha} u \|_{L^{2}(\Omega)}^{2} + \sum_{e \in \mathcal{E}_{D}} \left( \| r_{e_{c}} \mathbf{D}^{\alpha} u \|_{L^{2}(\omega_{e})}^{2} + \sum_{e \in \mathcal{E}_{N}} \| r_{e_{c}} \mathbf{D}^{\alpha} u \|_{L^{2}(\omega_{e})}^{2} \right) \\
+ \sum_{e \in \mathcal{C}_{D}} \left( \| r_{e_{c}} \mathbf{D}^{\alpha} u \|_{L^{2}(\omega_{e})}^{2} + \sum_{e \in \mathcal{E}_{N}} \| r_{e_{c}} \mathbf{D}^{\alpha} u \|_{L^{2}(\omega_{e})}^{2} \right) \end{array} \right.
\]

For \( m > k_{\beta} \), with
\[
k_{\beta} := - \min \left\{ \min_{c} \beta_{c}, \min_{e} \beta_{e} \right\},
\]
we denote by \( N_{h}^{m}(\Omega; \mathcal{C}_{D}, \mathcal{E}_{D}) \) the space of functions \( u \) such that \( \|u\|_{N_{h}^{m}(\Omega; \mathcal{C}_{D}, \mathcal{E}_{D})} < \infty \), with the norm
\[
\|u\|_{N_{h}^{m}(\Omega; \mathcal{C}_{D}, \mathcal{E}_{D})} := \sum_{k=0}^{m} \|u\|_{N_{h}^{k}(\Omega; \mathcal{C}_{D}, \mathcal{E}_{D})}^{2}.
\]

It follows from the definition of the norm \( \|u\|_{N_{h}^{m}(\Omega; \mathcal{C}_{D}, \mathcal{E}_{D})} \) that the spaces \( N_{h}^{m}(\Omega; \mathcal{C}_{D}, \mathcal{E}_{D}) \) are monotonic with respect to the sets \( \mathcal{C}_{D}, \mathcal{E}_{D} \) for \( \emptyset \subseteq \mathcal{C}_{D} \subseteq C \) and \( \emptyset \subseteq \mathcal{E}_{D} \subseteq E \), we have
\[
M_{h}^{m}(\Omega) := N_{h}^{m}(\Omega; \mathcal{C}_{D}, \mathcal{E}_{D}) \subseteq N_{h}^{m}(\Omega; \mathcal{C}_{D}, \mathcal{E}_{D}) \subseteq N_{h}^{m}(\Omega; \emptyset, \emptyset) := N_{h}^{m}(\Omega),
\]
where \( M_{h}^{m}(\Omega) \) is the weighted Sobolev space obtained as the closure of \( C_{c}^{\infty}(\Omega) \) with respect to the norm \( \|\cdot\|_{M_{h}^{m}(\Omega)} = \|\cdot\|_{N_{h}^{m}(\Omega; \mathcal{C}_{D}, \mathcal{E}_{D})} \). For subdomains \( K \subseteq \Omega \) we shall denote by \( \|\cdot\|_{N_{h}^{m}(K; \mathcal{C}_{D}, \mathcal{E}_{D})} \) the semi-norm (2.11) with all domains of integration replaced by their intersections with \( K \subseteq \Omega \), and likewise we shall use the norm \( \|\cdot\|_{N_{h}^{m}(K; \mathcal{C}_{D}, \mathcal{E}_{D})} \).
2.3. Analytic regularity of variational solutions. We adopt the following classes of analytic functions from [3].

Definition 2.1. For subdomains $K \subseteq \Omega$ and any subsets $C' \subset C$, $E' \subset E$, the space $B_{\beta}(K; C', E')$ consists of all functions $u$ such that $u \in N_{\beta}^{m}(K; C', E')$ for $m > k_{\beta}$, with $k_{\beta}$ as in (2.12), and such that there exists a constant $C_{u} > 0$ with the property that

$$
|u|_{N_{\beta}^{m}(K; C', E')} \leq C_{u}^{\kappa+1} k! \quad \forall k > k_{\beta}.
$$

(2.14)

Remark 2.2. The analytic class $B_{\beta}(\Omega) = B_{\beta}(\Omega; \emptyset, \emptyset)$ is closely related to the countably normed spaces $B_{\beta}(\Omega)$ introduced by Babuska and Guo in [2, 7, 8]: if the edge and corner exponents $\beta_{ij} \in (0, 1)$ and $\beta_{m} \in (0, 1/2)$ introduced in [2, 7, 8] satisfy $\beta_{ij} = \beta_{e} + \ell$ and $\beta_{m} = \beta_{e} + \ell$ for every $e \in C$ and $e \in E$, then $B_{\beta}(\Omega) = B_{\beta}(\Omega)$. By (2.13), we also have $A_{\beta}(\Omega) = B_{\beta}(\Omega; C, E)$, where $A_{\beta}(\Omega)$ is the analytic class considered in [11].

We have the following regularity result (see [3, Theorem 7.3]).

Proposition 2.3. There are bounds $b_{e}, b_{c} > 0$ (depending on $\Omega$ and on the space $V$) such that, for $b$ satisfying

$$
0 < b_{e} < b_{c}, \quad 0 < b_{c} < b_{e}, \quad e \in E, \quad c \in C,
$$

(2.15)

any weak solution $u \in V$ defined in (1.4) of problem (1.1)–(1.3) satisfies:

$$
f \in B_{1-b}(\Omega; C, E_{D}) \implies u \in B_{1-b}(\Omega; C, E_{D}).
$$

(2.16)

Remark 2.4. We may and will assume in the following without loss of generality that in (2.15) there holds $0 < b_{c}, b_{e} < 1$. Then $\beta_{e}, \beta_{c} \in (-2, -1)$ in (2.10). Consequently, we have $\kappa_{\beta} \in (1, 2)$ in (2.12), and (2.14) holds for all $k > 1$. Moreover, for $|\alpha^{+}| > 2$, there holds, $\max\{\beta_{e} + |\alpha^{+}|, 0\} = \beta_{e} + |\alpha^{+}|$.

Remark 2.5. Under the assumptions of Proposition 2.3, there holds

$$
B_{1-b}(\Omega; C, E_{D}) \subset C^{0}(\Omega).
$$

(2.17)

This inclusion is a consequence of Remark 2.2 above on the equivalence of weighted analytic spaces defined via (2.11), (2.14), with the spaces of Babuška and Guo introduced in [7, 8], under our assumption that $0 < b_{c}, b_{e} \leq 1$ (cp. Remark 2.4); see [8, Theorem 5.10]. The assertions (2.16) and (2.17) imply in particular that point values of the solution $u \in B_{1-b}(\Omega; C, E_{D})$ are well-defined at $E$ and $C$.

Remark 2.6. Note that the regularity (2.16) implies the a-priori estimates (2.14) in the weighted spaces with weights at all $e \in C$, even if $e$ is a “Neumann corner”, i.e. if only Neumann faces meet at corner $c$. In the case of corners $e$ of polyhedra in $\mathbb{R}^{3}$, corner weights do not imply homogeneous Dirichlet boundary conditions since by Hardy’s inequality $\{u \in H^{1}(\Omega) : r_{e}^{-1}u \in L^{2}(\Omega) : e \in C\} = H^{1}(\Omega)$ for bounded Lipschitz domains $\Omega \subset \mathbb{R}^{3}$. This implies that the Dirichlet corner weights do not contribute to the characterization of integrability of the weak solution $u \in V$ near the singular set $S$ which is, by (2.11), completely characterized by the edge weight functions for all edges $e \in E$, which meet at corner $c \in C$. The regularity (2.16) in the analytic class $B_{1-b}(\Omega; C, E_{D})$ implies $C_{D} = C$ in (2.11) so that only six out of the nine terms in the weighted semi-norms $|\cdot|_{N_{\beta}^{m}(\Omega; C, E_{D})}$ suffice to characterize the analytic regularity of $u$. In particular, the corner weights have the same structure as in the pure Dirichlet case, albeit with in general a larger range of the exponents $\beta_{c}$, whereas for each edge $e \in E$, the two cases $e \in E_{D}$ and $e \notin E_{D}$ must be distinguished.

The positivity of the indices $b_{e}, b_{c}$ in (2.15) implies with (2.10) that $-1 - \beta_{e} < -1, -1 - \beta_{c} < -1, \text{ and } 1 < k_{\beta} < 1 + \min\{\beta_{e}, \beta_{c}\}$. Inspection of (2.11) reveals that this forces the solution to zero weakly at Dirichlet edges $e \in E_{D}$; however, the structure of the weights $r_{e}^{\max\{\alpha_{e} + |\alpha^{+}|, 0\}}$ associated with Neumann edges $e \notin E_{D}$ in the third and sixth terms in (2.11) allows for nonzero traces of $u \in V$ at such edges.
3. hp-Subspaces in $\Omega$

In [10], we constructed a class of $hp$-DG spaces on families $\mathcal{M}_\sigma = \{\mathcal{M}_{\sigma, \ell}\}_{\ell \geq 1}$ of nested, $\sigma$-geometric meshes of hexahedral elements with $\ell$ layers of refinement, polynomial degree distributions which are nonuniform, anisotropic within elements and $s$-linearly increasing between elements. Here, we recapitulate the construction in the particular case of axiparallel domains and meshes, and refer to [10, Section 3] for details and proofs.

3.1. Geometric $hp$-Meshe in $\Omega$. We start from any coarse regular quasuniform partition $\mathcal{M}^0 = \{Q_j\}_{j=1}^J$ of $\Omega$ into $J$ convex axiparallel hexahedra. Each of these hexahedral elements $Q_j \in \mathcal{M}^0$ is the image under an affine mapping $G_j$ of the reference patch $\tilde{Q} = (-1, 1)^3$, i.e. $Q_j = G_j(\tilde{Q})$ for $j = 1, \ldots, J$. In fact, since the hexahedra $\{Q_j\}_j$ are assumed axiparallel, the mappings $G_j$ are compositions of (isotropic) dilations and translations. Due to our assumption that the faces of $\Omega$ are plane, it is geometrically exact.

In [10], canonical geometric mesh patches on the reference patch $\tilde{Q}$ have been constructed; see Figure 1. Geometric meshes towards corners and edges in $\Omega$ can then be obtained by again applying the patch mappings $G_j$ to transform these canonical geometric mesh patches on the reference patch $\tilde{Q}$ to the patches $Q_j \in \mathcal{M}^0$. It is important to note that the geometric refinements in the canonical patches have to be suitably selected and oriented in order to achieve a proper geometric refinement towards corners and edges of $\Omega$. In addition, we allow for simultaneous geometric refinement towards several edges. In [10, Section 3.3], a specific construction of geometric meshes has been introduced in terms of four different $hp$-extensions (Ex1)-(Ex4) as displayed in Figure 1. They also apply to our exponential convergence analysis below. Moreover, the patches $Q_j$ with $\tilde{Q}_j \cap S = \emptyset$ away from the singular support $S$ are left unrefined, i.e., no refinement is considered on $\tilde{Q}$.

Consider now the hexahedral patch $Q_j \in \mathcal{M}^0$. We denote the elements in the canonical geometric mesh patch associated with $Q_j$ by $\hat{M}_j = \{\hat{K}\}$, where we allow $\hat{M}_j = \{\hat{Q}\}$ in the case of unrefined patches. The elements in $\hat{M}_j$ are then transported to the physical domain $\Omega$ via the (finitely many) affine patch maps $G_j$. Moreover, for each $\hat{K} \in \hat{M}_j$, we can write $\hat{K} = H_{j, \hat{K}}(\tilde{K})$, where $H_{j, \hat{K}} : \tilde{K} \to \hat{K}$ is a possibly anisotropic dilation combined with a translation of the reference cube $\tilde{K} = (-1, 1)^3$ (to be distinguished from the reference patch $\tilde{Q}$). Thus, the elements in the patch $Q_j \subset \Omega$ will be given by $M_j = \{K : K = (G_j \circ H_{j, \hat{K}})(\tilde{K}), \tilde{K} \in \hat{M}_j\}, j = 1, \ldots, J$. A geometric mesh in $\Omega$ is now given by

$$
\mathcal{M} := \bigcup_{j=1}^J M_j. 
$$

Throughout, we shall assume that the initial mesh $\mathcal{M}^0$ is sufficiently fine so that an element $K \in M$ has non-trivial intersection with at most one corner $c \in C$ and at most one edge $e \in E$. By construction, each hexahedral element $K \in \mathcal{M}$ is the image of the reference cube $\tilde{K}$ under an element mapping $\Phi_K : K = \Phi_K(\tilde{K})$, which is a possibly anisotropic dilation with a translation from $\tilde{K}$ to $K$. We collect all element mappings $\Phi_K$ in the mapping vector $\Phi(\mathcal{M}) := \{\Phi_K : K \in \mathcal{M}\}$.

With each (axiparallel) element $K \in \mathcal{M}$ in the geometric mesh, let us associate a polynomial degree vector $p_K = (p_{K,1}, p_{K,2}, p_{K,3}) \in \mathbb{N}_0^3$. Its components correspond to the coordinate directions in $\tilde{K} = \Phi^{-1}_K(K)$. The polynomial degree is called isotropic if $p_{K,1} = p_{K,2} = p_{K,3} = p_K$. We set $|p_K| := \max_{i=1}^3 p_{K,i}$.

In the $hp$-error estimates, we shall often write $K$ in the form

$$
K := K^\perp \times K^\parallel, 
$$

where $K^\perp$ is an axiparallel rectangle of diameter $h_K^\perp$ in the first two coordinates $x^\perp = (x_1, x_2)$ perpendicular to the nearest edge $e$, and $K^\parallel$ is an interval of length $h_K^\parallel$ in the third coordinate direction $x^\parallel = x_3$ parallel to $e$. Analogously, we then choose $p_{K,1} = p_{K,2} =: p_K^\perp$, and write $p_K = (p_K^\parallel, p_K^\perp)$. 

Given a mesh $\mathcal{M}$ of hexahedral elements in $\Omega$, we combine the elemental polynomial degrees $p_K$ into the polynomial degree vector $\mathbf{p}(\mathcal{M}) := \{ p_K : K \in \mathcal{M} \}$, and define $p_{\text{max}} := \max_{K \in \mathcal{M}} |p_K|$. We remark that, in addition to the mesh refinements, the extensions (Ex1)–(Ex4) introduced in [10] also provide appropriate polynomial degree distributions that increase $\sigma$-linearly away from the singular set $\mathcal{S}$.

In the sequel, we shall be working with sequences of $\sigma$-geometrically refined meshes denoted by $\mathcal{M}_\sigma^{(0)}, \mathcal{M}_\sigma^{(1)}, \mathcal{M}_\sigma^{(2)}, \ldots, \mathcal{M}_\sigma^{(\ell)}, \ldots$, where $\mathcal{M}_\sigma^{(0)} := \mathcal{M}^0$. Here, $\sigma \in (0, 1)$ is a fixed parameter defining the ratio of subdivision in the canonical geometric refinements in Figure 1. We shall refer to the index $\ell$ as refinement level, and to the sequence $\mathcal{M}_\sigma = \{ \mathcal{M}_\sigma^{(\ell)} \}_{\ell \geq 1}$ as a $\sigma$-geometric mesh family; see [10, Definition 3.4].

3.2. Mesh Layers. As in [10, Section 3], we shall use the concept of mesh layers: these are partitions of $\mathcal{M}_\sigma = \{ \mathcal{M}_\sigma^{(\ell)} \}_{\ell \geq 1}$ into certain subsets of elements with identical scaling properties in terms of their relative distance to the sets $\mathcal{C}$ and $\mathcal{E}$. The following result holds.

**Proposition 3.1.** Any $\sigma$-geometric mesh family $\mathcal{M}_\sigma$ obtained by iterating the basic $hp$-extensions (Ex1)–(Ex4) in [10] can be partitioned into a countable sequence of disjoint mesh layers $\{ D_{\sigma}^{\ell} \}_{\ell = 0}^{\infty}$, and a corresponding nested sequence of terminal layers $\mathcal{T}_{\sigma}^{\ell}$, such that each $\mathcal{M}_\sigma^{(\ell)} \in \mathcal{M}_\sigma$, $\ell \geq 1$, can be written as

$$\mathcal{M}_\sigma^{(\ell)} = D_{\sigma}^{0} \cup D_{\sigma}^{1} \cup \ldots \cup D_{\sigma}^{\ell-1} \cup \mathcal{T}_{\sigma}^{\ell}.$$  \hfill (3.3)

Elements in the submesh

$$D_{\sigma}^{\ell} := \mathcal{O}_{\sigma}^{0} \cup \mathcal{O}_{\sigma}^{1} \cup \ldots \cup \mathcal{O}_{\sigma}^{\ell-1} \subset \mathcal{M}_\sigma^{(\ell)} \in \mathcal{M}_\sigma, \quad \ell \geq 1,$$  \hfill (3.4)

are bounded away from $\mathcal{C} \cup \mathcal{E}$, while all elements in the terminal layer $\mathcal{T}_{\sigma}^{\ell}$ have a nontrivial intersection with $\mathcal{C} \cup \mathcal{E}$. Evidently, $\mathcal{M}_\sigma^{(\ell)} = D_{\sigma}^{\ell} \cup \mathcal{T}_{\sigma}^{\ell}$ for $\ell \geq 1$.

We partition $D_{\sigma}^{\ell}$ into discrete corner, edge and corner-edge neighborhoods as $D_{\sigma}^{\ell} = D_{\text{int}}^{\ell} \cup D_{\text{C}}^{\ell} \cup D_{\text{CE}}^{\ell} \cup D_{\text{int}}^{\text{f}}$, where for $\ell \geq 1$,

$$D_{\text{int}}^{\ell} := \{ K \in D_{\sigma}^{\ell} : \mathcal{R} \cap \mathcal{O}_e = \emptyset \},$$

$$D_{\text{C}}^{\ell} := \{ K \in D_{\sigma}^{\ell} : \mathcal{R} \cap \mathcal{O}_c \neq \emptyset \} \setminus D_{\text{int}}^{\ell},$$

$$D_{\text{CE}}^{\ell} := \{ K \in D_{\sigma}^{\ell} : \mathcal{R} \cap \mathcal{O}_{ce} \neq \emptyset \} \setminus (D_{\text{int}}^{\ell} \cup D_{\text{C}}^{\ell} \cup D_{\text{int}}^{\text{f}}) \cup D_{\text{int}}^{\text{f}}.$$  \hfill (3.5)

Note that there exists $\ell_0 \geq 1$ (depending on $\varepsilon$ from (2.3) and on $\sigma$) such that $D_{\text{int}}^{\ell_0} = D_{\text{int}}^{\ell_0}$ for $\ell \geq \ell_0$. Without loss of generality, we shall assume that the initial mesh is sufficiently fine so that we can choose $\ell_0 = 2$. Consequently, in what follows we shall simply write $D_{\text{int}}$ instead of $D_{\text{int}}^{\ell_0}$. In addition, we may assume without loss of generality that $\mathcal{L}_0^{0} \subset D_{\text{int}}$ for $\ell \geq \ell_0 = 2$. 

*Figure 1.* Examples of three basic geometric mesh subdivisions in the reference patch $\tilde{Q}$ with subdivision ratio $\sigma = 1/2$: isotropic refinement towards the corner $c$ (left), anisotropic refinement towards the edge $e$ (center), and anisotropic refinement towards the edge-corner pair $ce$ (right). The sets $c, e, ce$ are shown in boldface.
For an element $K \in \mathcal{M}$, we set $h_K := \text{diam}(K)$, and denote by $h^1_K$ and $h^2_K$ the elemental diameters of $K$ transversally respectively parallel to the singular edge $e \in \mathcal{E}$ nearest to $K$; cp. [10]. For isotropic elements, we have $h^1_K \simeq h^2_K \simeq h_K$. In a sequence $\mathfrak{M}_\sigma = \{\mathcal{M}_\sigma^{(j)}\}_{j \geq 1}$ of $\sigma$-geometric meshes, we define for any $K \in \mathcal{M}_{\sigma}^{(j)}$, $c \in \mathcal{C}$ and $e \in \mathcal{E}$ the quantities:

$$d^e_K := \text{dist}(K, e) = \inf_{x \in K} r_e(x), \quad d^c_K := \text{dist}(K, c) = \inf_{x \in K} r_c(x).$$

(3.6)

These quantities are closely related to the elemental diameters $h^1_K$ and $h^2_K$; cp. [11, Prop. 3.2 & 3.4]. In particular, if $K = K^+ \times K^\| \in \mathcal{D}_\sigma^*$ as in (3.2), then $d^c_K \simeq h^2_K$, and $d^e_K \simeq h^1_K$.

Similarly, we partition the terminal layer $\mathcal{T}_e^s$ into $\mathcal{T}_e^c \cup \mathcal{T}_e^c$, where

$$\mathcal{T}_e^c := \bigcup_{c \in \mathcal{C}} \mathcal{T}_e^c, \quad \mathcal{T}_e^c := \{ K \in \mathcal{T}_s^c : \mathcal{K} \cap c \neq \emptyset \}, \quad c \in \mathcal{C},$$

(3.7)

$$\mathcal{T}_e^\ell := \bigcup_{e \in \mathcal{E}} \mathcal{T}_e^\ell, \quad \mathcal{T}_e^\ell := \{ K \in \mathcal{T}_s^\ell \setminus \mathcal{T}_e^c : (\mathcal{K} \cap e)^c \text{ is an entire edge of } K \}, \quad e \in \mathcal{E}. \quad (3.8)$$

For $\mathcal{M}^0$ sufficiently fine, we may assume that $\mathcal{T}_e^\ell$ consists of at most a finite number (independent of $c \in \mathcal{C}$, $\sigma$, and $\ell$) of elements $K \in \mathcal{T}_e^\ell$. According to [11, Proposition 3.2], these corner elements $K \in \mathcal{T}_e^c$ are isotropic with $h_K \simeq h^1_K \simeq h^2_K \simeq \sigma^\ell$, while elements in $K \in \mathcal{T}_e^\ell$ may be anisotropic with $d^e_K \lesssim h_K \simeq \sigma^\ell$, and $d^c_K \simeq h^1_K \simeq \sigma^{\ell+1-j}$ for an exponent $2 \leq j \leq \ell + 1$.

3.3. Finite Element Spaces. Let $\mathcal{M} = \mathcal{M}_{\sigma}^{(j)}$, for some $\ell$, be a geometric mesh of a $\sigma$-geometric mesh family $\mathfrak{M}_\sigma$ in $\Omega$. Furthermore, let $\Phi(\mathcal{M})$ and $p(\mathcal{M})$ be the associated element mapping and elemental polynomial degree vectors, as introduced above. We then introduce the discontinuous $hp$ finite element space

$$V(\mathcal{M}, \Phi, p) = \{ u \in L^2(\Omega) : u|_K \in Q_{p_K}(K), \, K \in \mathcal{M} \}. \quad (3.9)$$

Here, we define the local polynomial approximation space $Q_{p_K}(K)$ as follows: first, on the reference element $\hat{K}$ and for a polynomial degree vector $p = (p_1, p_2, p_3) \in \mathbb{N}_0^3$, we introduce the anisotropic polynomial space: $Q^p(\hat{K}) = \mathbb{P}_{p_1}(\hat{I}) \otimes \mathbb{P}_{p_2}(\hat{I}) \otimes \mathbb{P}_{p_3}(\hat{I}) = \text{span} \{ \hat{x}^\alpha : \alpha_1 \leq p_1, \, 1 \leq i \leq 3 \}$. Here, for $p \in \mathbb{N}_0$, we denote by $\mathbb{P}_p(\hat{I})$ the space of all polynomials of degree at most $p$ on the reference interval $\hat{I} = (-1,1)$. Then, if $K$ is a hexahedral element of $\mathcal{M}$ with associated elemental mapping $\Phi_K : \hat{K} \rightarrow K$ and polynomial degree vector $p_K = (p_{K,1}, p_{K,2}, p_{K,3})$, we define $Q_{p_K}(K) := \{ u \in L^2(\hat{K}) : [u|_K \circ \Phi_K] \in Q_{p_K}(\hat{K}) \}$. In the case where the polynomial degree vector $p_K$ associated with $K$ is isotropic, i.e., $p_{K,1} = p_{K,2} = p_{K,3} = p_K$, we simply write $Q_{p_K}(K) = Q_{p_K}(\hat{K})$. For technical reasons that will become clear in the analysis, we will assume throughout the paper that all polynomial degrees on elements $K \in \mathcal{T}_e^{(j)}$ are greater than or equal to 3.

We now introduce two families of $hp$-finite element spaces for the discontinuous Galerkin methods, both yield exponentially convergent approximations and are based on the $\sigma$-geometric mesh families $\mathfrak{M}_\sigma = \{\mathcal{M}_\sigma^{(j)}\}_{j \geq 1}$. The first family of $hp$-dG subspaces is defined by

$$V^e_{\sigma} := V(\mathcal{M}_\sigma^{(J)}, \Phi(\mathcal{M}_\sigma^{(J)}), p_1(\mathcal{M}_\sigma^{(J)})), \quad \ell \geq 1, \quad (3.10)$$

where the elemental polynomial degree vectors $p_K$ in $p_1(\mathcal{M}_\sigma^{(j)})$ are isotropic and uniform, given on each element $K \in \mathcal{M}_\sigma^{(j)}$ as $p_K = \text{max}(3,\ell)$. The second family of $hp$-dG subspaces is chosen as

$$V_{\sigma, a}^e := V(\mathcal{M}_\sigma^{(J)}, \Phi(\mathcal{M}_\sigma^{(J)}), p_2(\mathcal{M}_\sigma^{(J)})), \quad \ell \geq 1, \quad (3.11)$$

for an increment parameter $a > 0$. Here the polynomial degree vectors $p_2(\mathcal{M}_\sigma^{(j)})$ are linearly increasing with slope $a$ away from $S$, i.e., specifically, the polynomial degrees $p_K$ and $p_2_K$ within each element $K \in \mathcal{M}_\sigma^{(j)}$ increase linearly with the number of mesh layers between that element and the closest edge $e \in \mathcal{E}$ respectively the closed corner $c \in \mathcal{C}$ of $\Omega$, with the factor of proportionality (“slope” in the terminology of [6]) being $a > 0$; see [10, Section 3]. In the pure Neumann case ($J_D = \emptyset$) we consider the factor space $V_{\sigma, a}^e = V_{\sigma, a}^e / \mathbb{R}$. 

Remark 3.2. By construction, increasing the index $j$ in the mesh layers $\Omega_j^f$ corresponds to moving from inside the domain towards the singular set $S$, with $\Omega_0^f$ being the most inner layer, and the terminal layer $\Omega_\ell^f$ being the most outer layer abutting at $S$; see (3.3). While this numbering takes into account the scaling properties of $\Omega_j^f$, it is in contrast to the notion of $s$-linearly increasing polynomial degrees where the polynomial degree increases $s$-linearly away from the singular set into the interior of the domain; see also [10].

3.4. Properties of bounded variation. The spaces $V_{d}^f$ and $V_{d,s}^f$ defined in (3.10) and (3.11), respectively, satisfy bounded variation properties with respect to the local mesh sizes and polynomial degrees. These properties will be implicitly used in our analysis. To describe them, let $\mathfrak{M}_\sigma$ be the underlying $\sigma$-geometric mesh family. For any $M \in \mathfrak{M}_\sigma$, we define the set of all interior faces in $M$ by

$$\mathcal{F}_I(M) := \{ f = (\partial K^2 \cap \partial K^3)^o \neq \emptyset : K^2, K^3 \in M \}.$$ 

The set of all Dirichlet boundary faces is given by $\mathcal{F}_D(M) := \{ f = (\partial K \cap \partial \Omega)^o \neq \emptyset : \nu \in J_D \}$, and similarly, we denote by $\mathcal{F}_N(M)$ the set of all Neumann faces. In addition, let $\mathcal{F}(M) = \mathcal{F}_I(M) \cup \mathcal{F}_D(M) \cup \mathcal{F}_N(M)$ denote the set of all (smallest) faces of $M$. Furthermore, for an element $K \in M$, we denote the set of its faces by $\mathcal{F}_K = \{ f \in \mathcal{F}(M) : f \subset \partial K \}$. For $K \in M$ and $f \in \mathcal{F}_K$, we denote by $h_{K,f}^\perp$ the height of $K$ over the face $f$, i.e., the diameter of element $K$ in the direction transversal to $f$. Similarly, we denote by $p_{K,f}^\perp$ the polynomial degree of $p_K$ transversal to $f$ (defined as the corresponding component of $\Phi_K^\perp(f)$).

The geometric mesh family now satisfies the following property with respect to the local mesh sizes: there is a constant $\mu_1 \in (0,1)$ only depending on $\sigma$ and $M^0$ such that

$$\mu_1 \leq h_{K,f}^\perp / h_{K,f}^\perp \leq \mu_1^{-1},$$

for all interior faces $f \in \mathcal{F}_I(M)$, and $M \in \mathfrak{M}_\sigma$. Further, the family of degree vectors $p_2(M_{d,s}^f)_{\ell \geq 1}$ introduced in (3.11) satisfies a similar property with respect to the polynomial degree: there is a constant $\mu_2 \in (0,1)$ (depending on $s$) such that $\mu_2 \leq p_{K,f}^\perp / p_{K,f}^\perp \leq \mu_2^{-1}$, for all interior faces $f \in \mathcal{F}_I(M_{d,s}^f)$, and $\ell \geq 1$. Note that for the family $p_1(M_{d,s}^f)_{\ell \geq 1}$ in (3.10) this property is trivially satisfied.

4. Discontinuous Galerkin Discretization

In this section we present the $hp$-dG discretizations of (1.1)–(1.2) for which we shall prove exponential convergence. In addition, we shall adapt the stability and approximation results from [10, Section 4] to mixed boundary conditions. Throughout, $M \in \mathfrak{M}_\sigma$ denotes a generic $\sigma$-geometric mesh.

4.1. Trace operators and trace discretization parameters. We shall first recall the jump and average operators over faces; cp. [10, 11]. For this purpose, consider an interior face $f \in \mathcal{F}_I(M)$ shared by two elements $K^2, K^3 \in M$. Furthermore, let $v$ respectively $w$ be a scalar respectively vector-valued function that is sufficiently smooth inside the elements $K^2, K^3$. Then we define the following jumps and averages of $v$ and $w$ along $f$:

$$[v] = v|_{K^2} n_{K^2} + v|_{K^3} n_{K^3}, \quad \langle v \rangle = \frac{1}{2} (v|_{K^2} + v|_{K^3}),$$

$$[w] = w|_{K^2} n_{K^2} + w|_{K^3} n_{K^3}, \quad \langle w \rangle = \frac{1}{2} (w|_{K^2} + w|_{K^3}).$$

Here, for an element $K \in M$, we denote by $n_K$ the outward unit normal vector on $\partial K$. For a Dirichlet boundary face $f \in \mathcal{F}_D(M)$ belonging to $K \in M$, we let $[v] = v|_{K} n_{\Omega_2}$, $[w] = w|_{K} n_{\Omega_2}$, and $\langle v \rangle = v|_{K}$, $\langle w \rangle = w|_{K}$, where $n_{\Omega_2}$ is the outward unit normal vector on $\partial \Omega$.

Moreover, we define the trace discretization parameters $h, p \in L^\infty(\mathcal{F}_I(M) \cup \mathcal{F}_D(M))$ by

$$h_f := h_{|f} := \min \{ h_{K,f}^\perp, h_{K,f}^\perp \}, \quad p_f := p_{|f} := \max \{ p_{K,f}^\perp, p_{K,f}^\perp \},$$

for any interior face $f \in \mathcal{F}_I(M)$ shared by $\partial K^2$ and $\partial K^3$. For a Dirichlet boundary face $f \in \mathcal{F}_D(M)$ shared by $\partial K$ and $\Gamma_\nu$, $\nu \in J_D$, we set accordingly $h_f := h_{|f} = h_{K,f}^\perp$, $p_f := p_{|f} = p_{K,f}^\perp$. 

4.2. \textit{hp-IP dGFEM.} The problem (1.1)-(1.3) will be discretized using an interior penalty (IP) discontinuous Galerkin finite element method. Let \( V(\mathcal{M}, \Phi, p) \) be an \( hp \)-\textit{dG} finite element space on a \( \sigma \)-geometric mesh \( \mathcal{M} \in \mathcal{M}_\sigma \), with a degree vector \( p(\mathcal{M}) \). For a fixed parameter \( \theta \in \mathbb{R} \), we define the \( hp \)-discontinuous Galerkin solution \( u_{\text{DG}} \) by

\[
 u_{\text{DG}} \in V(\mathcal{M}, \Phi, p) : \quad a_{\text{DG}}(u_{\text{DG}}, v) = \int_{\Omega} fv \, dx \quad \forall v \in V(\mathcal{M}, \Phi, p),
\]  

(4.2)

where the bilinear form \( a_{\text{DG}}(u, v) \) is given by

\[
a_{\text{DG}}(u, v) := \int_{\Omega} \nabla_h u \cdot \nabla_h v \, dx - \int_{\mathcal{F}_I(\mathcal{M})} \langle \langle \nabla_h w \rangle \rangle \cdot [v] \, ds + \theta \int_{\mathcal{F}_I(\mathcal{M}) \cup \mathcal{F}_D(\mathcal{M})} \langle \langle \nabla_h w \rangle \rangle \cdot [v] \, ds + \gamma \int_{\mathcal{F}_I(\mathcal{M}) \cup \mathcal{F}_D(\mathcal{M})} j \, [v] \cdot [w] \, ds.
\]

Here, \( \nabla_h \) is the elementwise gradient operator, and \( \gamma > 0 \) is a stabilization parameter that will be chosen sufficiently large. Furthermore, \( j \) is facewise defined as

\[
j | f = p_f^2 h_f^{-1}, \quad f \in \mathcal{F}_I(\mathcal{M}) \cap \mathcal{F}_D(\mathcal{M}).
\]

(4.3)

Finally, the parameter \( \theta \) allows us to describe a whole range of interior penalty methods: for \( \theta = -1 \) we obtain the standard symmetric interior penalty (SIP) method while for \( \theta = 1 \) the non-symmetric (NIP) version is obtained; cp. \([1]\) and the references therein.

To address the well-posedness of the \( hp \)-dGFEM, we use the standard dG norm defined by

\[
\| v \|_{DG}^2 = \int_{\Omega} |\nabla_h v|^2 \, dx + \gamma \int_{\mathcal{F}_I(\mathcal{M}) \cup \mathcal{F}_D(\mathcal{M})} j \| v \|^2 \, ds,
\]

(4.4)

for any \( v \in V(\mathcal{M}, \Phi, p) + H^1(\Omega) \). In the pure Neumann case \( (\mathcal{F}_D(\mathcal{M}) = \emptyset) \), \( \| \cdot \|_{DG} \) is a norm on the subspace \( (V(\mathcal{M}, \Phi, p) + H^1(\Omega))/\mathbb{R} \).

4.3. \textit{Galerkin orthogonality and stability properties.} In order to show the well-posedness of the dG formulation (4.2), we recall first the anisotropic trace inequality from \([10, \text{Lemma 4.2}]\):

\[
\text{Proposition 4.2.} \quad \text{Let} \quad \mathcal{M} \in \mathcal{M}_\sigma, \quad 0 < \sigma < 1, \quad K \in \mathcal{M}, \quad f \in \mathcal{F}_K. \quad \text{For} \quad 1 \leq q < \infty \quad \text{there exists} \quad C_q > 0 \quad \text{such that for any} \quad v \in W^{1,q}(K) \quad \text{holds}
\]

\[
\| v \|^q_{L^q(K)} \leq C_q \left( h_{K,f}^{-1} \left( \| v \|_{L^q(K)} + (h_{K,f})^{\frac{q}{2}} \| \partial_{K,f \perp} v \|_{L^q(K)} \right) \right). \tag{4.5}
\]

The constant \( C_q > 0 \) is independent of the element size and of the element aspect ratio, and \( \partial_{K,f \perp} \) signifies the partial derivative with respect to the (local coordinate) direction transversal to \( f \in \mathcal{F}_K \).

Secondly, the following \textit{Galerkin orthogonality} is crucial in the subsequent dG error analysis.

\[
\text{Lemma 4.1.} \quad \text{Let} \quad \mathcal{M} \in \mathcal{M}_\sigma, \quad 0 < \sigma < 1, \quad K \in \mathcal{M}, \quad f \in \mathcal{F}_K. \quad \text{For} \quad 1 \leq q < \infty \quad \text{there exists} \quad C_q > 0 \quad \text{such that for any} \quad v \in V(\mathcal{M}, \Phi, p) \quad \text{from (4.2) satisfies} \quad a_{DG}(u - u_{DG}, v) = 0 \quad \text{for any} \quad v \in V(\mathcal{M}, \Phi, p).
\]

\[
\text{Proposition 4.2.} \quad \text{Suppose that the solution} \quad u \quad \text{of (1.1)-(1.3) belongs to} \quad N^q_{-1-\sigma}(\Omega; \mathcal{C}, \mathcal{E}_D), \quad \text{where} \quad \mathbf{b} \quad \text{is the weight vector from (2.15)} \quad \text{Then, the dG approximation} \quad u_{DG} \quad \text{from (4.2) satisfies} \quad a_{DG}(u - u_{DG}, v) = 0 \quad \text{for any} \quad v \in V(\mathcal{M}, \Phi, p).
\]

\[
\text{Proof.} \quad \text{The proof is similar to the one of [10, Theorem 4.9], and follows from the fact that the solution} \quad u \quad \text{satisfies} \quad a_{DG}(u, v) = 0. \quad \text{To prove this identity, we first note that, for any} \quad u \in \mathcal{N}^q_{-1-\sigma}(\Omega; \mathcal{C}, \mathcal{E}_D) \quad \text{and} \quad v \in V(\mathcal{M}, \Phi, p), \quad \text{there holds the Green's formula}
\]

\[
\int_K v \Delta u \, dx = \int_K \nabla u \cdot \nabla v \, dx - \int_{\partial K} (\nabla u \cdot \mathbf{n}_K) v \, ds, \quad \forall K \in \mathcal{M}, \tag{4.6}
\]

where in the case \( \partial K \cap \partial \Omega \neq \emptyset \), the boundary term has to be understood as a pairing in \( L^1(\partial K) \times L^\infty(\partial K) \). The formula (4.6) is proved along the lines of \([10, \text{Lemma 4.8}]\) with the aid of Lemma 4.1 with \( q = 1 \). Employing (4.6), the term \( \int_{\Omega} A \nabla u \cdot \nabla_h v \, dx \) can be integrated by parts on each element, thereby revealing that \( -\int_{\Omega} \nabla u \Delta v \, dx = \int_{\Omega} f v \, dx \). Here, the remaining boundary and inter-element flux terms vanish since \( \| u \|_{\partial K} = 0 \) along all \( f \in \mathcal{F}_D(\mathcal{M}) \cup \mathcal{F}_I(\mathcal{M}) \), and that \( \| \nabla u \|_{\partial K} = 0 \) on all interior faces \( f \in \mathcal{F}_I(\mathcal{M}) \). The proof of the latter identity is similar to the proof of \([10, \text{Lemma 4.7}]\).
Finally, the following proposition results from minor modifications of the proofs of the corresponding stability results presented in [10, Theorem 4.4].

Proposition 4.3. For any $\sigma$-geometric mesh $M$ and degree vector $p(M)$, the bilinear form $a_{DG}$ is continuous and coercive on $V(M, \Phi, p)$: there exist constants $0 < C_2 \leq C_1 < \infty$ independent of the refinement level $\ell$, the local mesh sizes and the local polynomial degree vectors such that $|a_{DG}(v, w)| \leq C_1 \|v\|_{DG} \|w\|_{DG}$ for all $v, w \in V(M, \Phi, p)$, and such that, for $\gamma > 0$ sufficiently large independent of the refinement level $\ell$, the local mesh sizes and the local polynomial degree vectors we have $a_{DG}(v, v) \geq C_2 \|v\|^2_{DG}$ for all $v \in V(M, \Phi, p)$. In particular, there exists a unique solution $u_{DG}$ of (4.2) (unique up to constants in the pure Neumann case).

5. Error analysis and exponential convergence

We begin the error analysis by choosing the approximation operators for elements $D_\sigma$ and $T_\sigma$, respectively, and by establishing some of their properties. Then we derive generic error estimates along the lines of those presented in [11]. Finally, we state our main result: an exponential convergence bound in the $dG$-norm $\| \cdot \|_{DG}$ for solutions $u \in B_{-b}(\Omega; C, E_D)$ as in Proposition 2.3.

5.1. The elemental approximation operators. Let $u$ be the solution of (1.1)–(1.3). In this section, we specify a polynomial approximation operator $\Pi u \in V(M, \Phi, p)$. Since functions in $V(M, \Phi, p)$ are discontinuous, we choose $\Pi u$ elementwise as $(\Pi u)|_K = \Pi_K u|_K$ for any $K \in M$.

5.1.1. $L^2$-projection in one dimension. For a generic, bounded interval $I = (a, b)$, we write $\pi_p$ for the $L^2$-projection into the space $P_p(I)$ of degree at most $p \geq 0$ on $I$ (for simplicity we do not explicitly indicate the dependence of $\pi_p$ on $I$: this dependence will always be clear from the context). For the purpose of scaling arguments, we further denote by $\hat{\pi}_p$ the $L^2$-projection on the reference interval $\hat{I} = (-1, 1)$. The following ($p$-dependent) stability properties with respect to Sobolev semi-norms will play a crucial role in our analysis.

Lemma 5.1. Let $I = (a, b)$ be an interval of size $h = b - a$, $p \geq 0$, and $v \in H^j(I)$ for $j \in \mathbb{N}_0$. Then, for every $p \geq j$, there holds the bound

$$\|(\pi_p u)^{(j)}\|_{L^2(I)} \leq C p^{2j} \|u^{(j)}\|_{L^2(I)},$$

(5.1)

where $C > 0$ is a constant depending only on $j$.

Proof. The $L^2$-stability of $\pi_p$ on $I$, that is the case $j = 0$, is clear and the inequality holds with constant $C = 1$. Next, consider the case $j \geq 1$. Upon scaling it is sufficient to consider the interval $I = (-1, 1)$. For $p \geq j$, it holds that $(\hat{\pi}_p(u))^{(j)} \in \mathbb{P}_{p-j}(\hat{I})$, and, for the $L^2$-projections $\hat{\pi}_{j-1}(u) \in \mathbb{P}_{j-1}(\hat{I})$, $j = 1, 2, \ldots$, we have that

$$\|(\hat{\pi}_p(u))^{(j)}\|_{L^2(\hat{I})} = \|(\hat{\pi}_p(u) - \hat{\pi}_{j-1}(u))^{(j)}\|_{L^2(\hat{I})} = \|(\hat{\pi}_p(u) - \hat{\pi}_{j-1}(u))^{(j)}\|_{L^2(\hat{I})}.$$

Hence, applying the inverse inequality from [12, Theorem 3.91], yields

$$\|(\hat{\pi}_p(u))^{(j)}\|_{L^2(\hat{I})} \leq C_{inv,j} p^{2j} \|u - \hat{\pi}_{j-1}(u)\|_{L^2(\hat{I})},$$

and employing a Poincaré-type inequality in $H^j(\hat{I})/\mathbb{P}_{j-1}(\hat{I})$, results in

$$\|(\hat{\pi}_p(u))^{(j)}\|_{L^2(\hat{I})} \leq C_{inv,j} p^{2j} C_{Poinc,j} \|u^{(j)}\|_{L^2(\hat{I})}.$$

This is the desired estimate.\hfill $\square$

5.1.2. Approximation on $K \in D_\sigma^e$. For an interior element $K \in D_\sigma^e$, we now construct the tensor-product $L^2$-projection $\Pi_{p_k} u$ as follows. In the setting of (3.2), we write $K = K^\perp \times K^\parallel$, and let $p_K = (p_K^\perp, p_K^\parallel)$. Then we define

$$\Pi_{p_k} u|_K := \left(\Pi_{p_K^\perp} u \circ \Phi_K^\perp\right) \circ \Phi_K^\perp^{-1}$$

$$= \left(\hat{\pi}_{p_K^\perp}^{(1)} \hat{\pi}_{p_K^\perp}^{(2)} \hat{\pi}_{p_K^\perp}^{(3)} \circ \Phi_K^\perp\right) (u \circ \Phi_K) \circ \Phi_K^\perp^{-1} \in Q_{p_{K^\perp}}(K^\perp) \otimes Q_{p_{K^\parallel}}(K^\parallel),$$

(5.2)

where the one-dimensional $L^2$-projections act in directions $x_1$, $x_2$, and $x_3$, respectively.
It will be further necessary to distinguish between the perpendicular and parallel projections. To that end, we write
\[ \Pi_{pK} u = (\Pi_{\perp pK}^L \otimes \Pi_{\perp pK}^\parallel) u, \quad K \in \mathcal{O}_h, \]  \hspace{1cm} (5.3)
where \((\Pi_{\perp pK}^L)_{\mid K} = \left( \hat{\pi}_{pK}^{(1)} \otimes \hat{\pi}_{pK}^{(2)} \right) (u \circ \Phi_K) \circ \Phi_K^{-1}, \) and \(\Pi_{\perp pK}^\parallel u = \hat{\pi}_{pK}^{(3)} (u \circ \Phi_K) \circ \Phi_K^{-1}.\)

5.1.3. A low-order \(P_1\)-approximation operator. We require the following \(P_1\)-quasi-interpolation operator considered in [5]. Let \(\mathcal{R} \subset \mathbb{R}^d\) be a bounded, convex polygonal \((d = 2)\) or convex polyhedral \((d = 3)\) domain which is shape-regular, with diameter \(h_{\mathcal{R}},\) and whose barycenter is
\[ x_{\mathcal{R}} = \frac{1}{|\mathcal{R}|} \int_{\mathcal{R}} x \, dx \in \mathcal{R}, \]  \hspace{1cm} (5.4)
where \(|\mathcal{R}|\) denotes the volume of \(\mathcal{R}\). Then, by definition of \(x_{\mathcal{R}}\),
\[ \int_{\mathcal{R}} (x - x_{\mathcal{R}}) \, dx = 0. \]  \hspace{1cm} (5.5)
Define the quasi-interpolation operator \(I_1 : W^{1,1}(\mathcal{R}) \rightarrow P_1(\mathcal{R})\) by
\[ I_1 v := \Pi_0 v + (x - x_{\mathcal{R}}) \cdot \Pi_0(\nabla v), \]  \hspace{1cm} (5.6)
where \(P_1(\mathcal{R})\) denotes the polynomials of total degree at most 1 on \(\mathcal{R},\) and where \(\Pi_0\) and \(\Pi_0\) denote element averages, i.e., the projections onto \(P_0(\mathcal{R})\) and on \(P_0(\mathcal{R})^d, \quad d = 2, 3,\) respectively.

**Lemma 5.2.** For the quasi-interpolation operator \(I_1\) defined in (5.6), there holds:
1. \(\nabla(I_1 v) = \Pi_0(\nabla v)\) on \(\mathcal{R}\) for all \(v \in W^{1,1}(\mathcal{R}).\)
2. \(\int_{\mathcal{R}} (v - I_1 v) \, dx = 0\) and \(\int_{\mathcal{R}} \nabla(v - I_1 v) \, dx = 0\) for all \(v \in W^{1,1}(\mathcal{R}).\)
3. For \(1 \leq q \leq \infty,\) the quasi-interpolant \(I_1\) is \(W^{1,q}(\mathcal{R})\)-stable in the following sense:
\[ \forall v \in W^{1,q}(\mathcal{R}): \quad \|\nabla(I_1 v)\|_{L^q(\mathcal{R})} \leq \|\nabla v\|_{L^q(\mathcal{R})}. \]  \hspace{1cm} (5.7)
4. For \(v \in H^1(\mathcal{R})\) hold the approximation properties:
\[ \|v - I_1 v\|_{L^2(\mathcal{R})} \lesssim h_{\mathcal{R}} \|\nabla v\|_{L^2(\mathcal{R})}, \quad \|v - I_1 v\|_{L^2(\mathcal{R})} \lesssim h_{\mathcal{R}}^{1/2} \|\nabla v\|_{L^2(\mathcal{R})}. \]  \hspace{1cm} (5.8)
5. If \(v \in H^2(\mathcal{R}),\) there holds
\[ \|v - I_1 v\|_{L^2(\mathcal{R})} + h_{\mathcal{R}} \|\nabla(v - I_1 v)\|_{L^2(\mathcal{R})} \lesssim h_{\mathcal{R}}^2 \|v\|_{H^2(\mathcal{R})}. \]
6. Let \(d = 2,\) and \(c\) a corner of \(\mathcal{R},\) and denote \(r = r(x) = \text{dist}(x, c).\) If \(\|r^\beta D^\alpha v\|_{L^2(\mathcal{R})} < \infty,\) for any \(|\alpha| = 2\) and some \(0 < \beta < 1,\) then, with an implied constant depending on the shape-regularity of \(\mathcal{R},\) we have
\[ \|v - I_1 v\|_{L^2(\mathcal{R})} + h_{\mathcal{R}} \|\nabla(v - I_1 v)\|_{L^2(\mathcal{R})} \lesssim h_{\mathcal{R}}^{2-\beta} \sum_{|\alpha|=2} \|r^\beta D^\alpha v\|_{L^2(\mathcal{R})}. \]  \hspace{1cm} (5.9)

**Proof.** We prove this lemma item by item.
1. The first item follows immediately from the definition of \(I_1\) in (5.6).
2. Moreover, note that
\[ v - I_1 v = (v - \Pi_0 v) - (x - x_{\mathcal{R}}) \cdot \Pi_0(\nabla v). \]  \hspace{1cm} (5.10)
Integrating this identity over \(\mathcal{R},\) the second item follows from property (5.5) and from \(\int_{\mathcal{R}} (v - \Pi_0 v) \, dx = 0.\)
3. For \(1 \leq q < \infty,\) the \(W^{1,q}(\mathcal{R})\)-stability property results by noticing that \(\Pi_0(\nabla v)\) is constant, and from Hölder’s inequality:
\[ \|\nabla(I_1 v)\|_{L^q(\mathcal{R})} = \|\Pi_0(\nabla v)\|_{L^q(\mathcal{R})} = \|\mathcal{R}\|^{1/q} \|1\|_{L^{q/(q-1)}(\mathcal{R})} \leq \|\nabla v\|_{L^q(\mathcal{R})}. \]
For \(q = \infty\) the proof is similar.
5.1.4. This completes the proof. □

Then we set

\[ e \in \mathcal{E} \] for some direction to \( e \) as in (5.3). Finally, for a corner element \( K \in \mathcal{T}_h^e \) as in (3.7), we set

\[ (\Pi u)|_K = \mathcal{I}_e(u)|_K, \quad K \in \mathcal{T}_h^e, \]  

(5.11)

where \( \mathcal{I}_e \) is the two-dimensional \( P_1 \)-projector defined in (5.6) and applied in perpendicular direction to \( e \) with \( \mathcal{R} = K^\perp \), and \( \Pi^{\perp}_p \) is the \( L^2 \)-projection onto polynomials of degree \( p_K \) in parallel direction to \( e \) as in (5.3). Finally, for a corner element \( K \in \mathcal{T}_h^e \) as in (3.7), we set

\[ (\Pi u)|_K := \mathcal{I}_e(u)|_K \]  

(5.12)

5.1.5. Tensor-product structure of \( \Pi \) on \( \mathcal{D}^e_0 \) and \( \mathcal{T}^e_\sigma \). On elements \( K = K^\perp \times K^\parallel \) in \( \mathcal{D}^e_0 \) and \( \mathcal{T}^e_\sigma \), the approximation operator \( \Pi u \) chosen in (5.2), (5.3), and (5.11) has tensor-product structure. In what follows, we shall now simply write

\[ (\Pi u)|_K = \Pi_K u|_K = \Pi_K^\perp \otimes \Pi_K^\parallel u|_K = (\Pi^\perp \otimes \Pi^\parallel u)|_K, \quad K \in \mathcal{D}^e_0 \cup \mathcal{T}^e_\sigma. \]  

(5.13)

**Lemma 5.3.** Let \( K \in \mathcal{D}^e_0 \cup \mathcal{T}^e_\sigma \). Then \( \Pi \) in (5.13) satisfies:

1. The operator \( \Pi_K^\perp \) is the \( L^2 \)-projection in edge-parallel direction into polynomials in \( P_{p_K}^\parallel (K^\parallel) \), and \( \Pi_K^\parallel \) is an approximation operator from \( H^1(K^\parallel) \) into \( Q_{p_K}^\parallel (K^\parallel) \) (respectively \( P_{p_K}^\parallel (K^\parallel) \) in elements \( K \) in the terminal layers).
2. The operator \( \Pi_K^\perp \) reproduces polynomials in \( Q_{p_K}^\parallel (K^\parallel) \) (respectively \( P_{p_K}^\parallel (K^\parallel) \) in elements \( K \) in the terminal layers).
3. The operator \( \Pi_K^\parallel \) satisfies the approximation property:

\[ \| v - \Pi_K^\parallel v \|_{L^2(K^\parallel)} \leq h_K \cdot \| D_{\perp} v \|_{L^2(K^\parallel)}, \quad v \in H^1(K^\parallel), \]  

(5.14)

**Proof.** The first two properties follow by construction. The trace approximation bound (5.14) is a standard result for the two-dimensional \( L^2 \)-projection \( \Pi_K^\parallel = P_{p_K}^\parallel \) in (5.3). For \( \Pi_K^\perp = \mathcal{I}_e^\perp \) in (5.11) this follows from (5.8) in Lemma 5.2. □
If now \( u \) is the solution of (1.1)–(1.3), and \( \Pi \) the tensor product projection introduced in (5.13), we shall always denote by \( \eta \) the approximation error
\[
\eta|_K := u|_K - (\Pi u)|_K, \quad K \in \mathcal{M}.
\]
(5.15)

In accordance with (5.13), we also set
\[
\eta^\perp|_K := u|_K - (\Pi^\perp u)|_K, \quad \eta^\parallel|_K := u|_K - (\Pi^\parallel u)|_K, \quad K \in \mathcal{D}_\rho^f \cup \mathcal{T}_\rho^f.
\]
(5.16)

For \( K \in \mathcal{D}_\rho^f \cup \mathcal{T}_\rho^f \), we shall further split \( \eta|_K \) into
\[
\eta|_K = (u|_K - (\Pi^\parallel u)|_K) + \Pi^\perp (u|_K - (\Pi^\perp u)|_K) = \eta^\parallel|_K + \Pi^\parallel \eta^\perp|_K.
\]
(5.17)

The stability of the \( L^2 \)-projection in (5.1), and the commutativity of the \( L^2 \)-projectors in perpendicular and parallel direction yields
\[
\|D^\alpha_\perp D^\alpha_\parallel \eta^\parallel\|_{L^2(K)} \lessapprox (\|D^\alpha_\perp D^\alpha_\parallel \eta\|_{L^2(K)} + \|D^\alpha_\perp D^\alpha_\parallel \eta^\perp\|_{L^2(K)}),
\]
(5.18)

for any \( \alpha^\perp \in \mathbb{N}_0^2 \), and \( 0 \leq a^\parallel \leq 2 \), with \( \lessapprox \) uniform in the aspect ratio of \( K \).

5.2. **An anisotropic jump estimate.** The following bound is crucial for controlling the consistency error in anisotropic elements in the terminal layers near Neumann edges.

**Proposition 5.4.** Consider an interior face \( f = (\partial K_1 \cap \partial K_2)^2 \) that is parallel to the closest edge \( e \in \mathcal{E} \), and which is shared by two axiparallel elements \( K_1 = K_1^\parallel \times K_1^\perp \) and \( K_2 = K_2^\parallel \times K_2^\perp \) of possibly high aspect ratios \( (b^\parallel - a^\parallel)/h_{K_2^\parallel} \), where \( K_1 = (a^\parallel, b^\parallel) \), and \( h_{K_i} = b^\parallel - a^\parallel \) denotes the element size in edge-parallel direction, and \( K_1^\parallel \) and \( K_2^\parallel \) are two neighboring (but possibly non-matching) rectangles in edge-perpendicular direction such that the bounded variation property (3.12) holds. Moreover, for \( u \in H^1((K_1 \cup K_2)^2) \), we let \( \Pi^\parallel_{K_i} = \Pi^\perp_{K_i} \otimes \Pi^\parallel_{K_i} \) be a tensor-product quasi-interpolation operator as in (5.13) satisfying properties (1)–(3) in Lemma 5.3 for \( i = 1, 2 \). Then for \( \eta, \eta^\parallel \) and \( \eta^\perp \) as in (5.15), (5.16), there holds
\[
|||\eta|||_{L^2(f)}^2 \lessapprox \|D_\perp \eta^\parallel\|^2_{L^2(K_1)} + \|D_\parallel \eta^\perp\|^2_{L^2(K_2)}.
\]
(5.19)

**Proof.** Since \( \Pi^\parallel_{K_i} \) reproduces polynomials in perpendicular direction, we see that
\[
\eta^\parallel - \Pi^\parallel_{K_i} \eta^\parallel = (u - \Pi^\parallel_{K_i} u) - \Pi^\parallel_{K_i} (u - \Pi^\parallel_{K_i} u) = u - \Pi^\parallel_{K_i} u = \eta^\parallel,
\]
on \( K_i \), \( i = 1, 2 \). Since \( \|\eta\| = \|\Pi u\| \) and \( \Pi^\parallel u \cap K_i = \Pi^\parallel_{K_i} u \cap K_i \) on \( f \), we obtain
\[
|||\eta|||_{L^2(f)}^2 = \int_f \left( \Pi^\perp_{K_1} \otimes \Pi^\parallel_{K_1} u \cap K_1 - \Pi^\perp_{K_2} \otimes \Pi^\parallel_{K_2} u \cap K_2 \right)^2 \, ds
\]
\[
= \int_f \left( \Pi^\perp_{K_1} \otimes \Pi^\parallel_{K_1} u \cap K_1 - \Pi^\parallel_{K_1} u \cap K_1 \right) - \Pi^\perp_{K_2} \otimes \Pi^\parallel_{K_2} u \cap K_2\right)^2 \, ds
\]
\[
\lessapprox \int_f \left( \Pi^\parallel_{K_1} \eta^\parallel \cap K_1 \right)^2 \, ds + \int_f \left( \Pi^\parallel_{K_2} \eta^\parallel \cap K_2 \right)^2 \, ds.
\]

Applying (5.14) in perpendicular direction and the \( L^2 \)-stability of the \( L^2 \)-projection \( \Pi^\parallel_{K_i} \) yields
\[
|||\eta|||_{L^2(f)}^2 \lessapprox h_{K_1}^\parallel |||\Pi^\parallel D_\parallel \eta^\parallel|||_{L^2(K_1)}^2 + h_{K_2}^\parallel |||\Pi^\parallel D_\perp \eta^\perp|||_{L^2(K_2)}^2
\]
\[
\lessapprox h_{K_1}^\parallel |||D_\perp \eta^\parallel|||_{L^2(K_1)}^2 + h_{K_2}^\parallel |||D_\perp \eta^\parallel|||_{L^2(K_2)}^2.
\]
By the definition of \( h_f \), the bounded variation property (3.12) and the equivalence of \( h_{K_1} \simeq h_{K_2} \), we remark that \( h_f \simeq h_{K_1}^\parallel \simeq h_{K_2}^\parallel \simeq h_{K_1}^\parallel \simeq h_{K_2}^\parallel \), which implies (5.19). \( \Box \)
5.3. Error estimates. To derive error estimates, we proceed in a standard way and split the discretization error \( e_{\text{DG}} = u - u_{\text{DG}} \) into two parts \( \eta \) and \( \xi \), \( e_{\text{DG}} = \eta + \xi \), with

\[
\eta|_K = (u - \Pi u)|_K \quad \xi|_K = ((\Pi u - u_{\text{DG}})|_K, \quad K \in \mathcal{M}_\ell^f (\Omega).
\]

(5.20)

Here, \( \Pi u \in \mathcal{V}(\mathcal{M}, \Phi, p) \) is a polynomial approximation operator as in Section 5.1.

In accordance with the partition of \( \mathcal{M}_\ell^f \) in (3.3), (3.7), and (3.8), we define the error terms

\[
\mathcal{T}_\mathcal{D}_\ell^f [\eta] := \sum_{K \in \mathcal{D}_\ell^f} T^K_\mathcal{D}[\eta], \quad \mathcal{T}_\mathcal{E}_{\ell, \perp}^f [\eta] := \sum_{K \in \mathcal{E}_{\ell, \perp}^f} T^K_e[\eta], \quad \mathcal{T}_\mathcal{E}_{\ell, D}^f [\eta] := \sum_{K \in \mathcal{E}_{\ell, D}^f} T^K_e[\eta],
\]

(5.21)

for \( i = 1, 2 \), where

\[
T^K_\mathcal{D} [\eta] := (h_K^3)^{-2} \eta \| \nabla \eta \|_{L^2(K)}^2 + (h_K^2)^2 \| \nabla \eta \|_{L^2(K)} \| \nabla \eta \|_{L^2(K)} + (h_K^2)^2 \| \nabla \eta \|_{L^2(K)}^2,
\]

(5.22)

\[
T^K_{e,1} [\eta] := (h_K^2)^{-2} \eta \| \nabla \eta \|_{L^2(K)}^2 + (h_K^2)^2 \| \nabla \eta \|_{L^2(K)} \| \nabla \eta \|_{L^2(K)} + (h_K^2)^2 \| \nabla \eta \|_{L^2(K)}^2,
\]

(5.23)

\[
T^K_{e,2} [\eta] := |K|^{-1} (h_K^2)^2 \| \nabla \eta \|_{L^2(K)}^2,
\]

(5.24)

\[
T^K_e [\eta] := h_K^{-2} \| \nabla \eta \|_{L^2(K)}^2 + \| \nabla \eta \|_{L^2(K)} + h_K^{-1} \| \nabla \eta \|_{L^2(K)}.
\]

(5.25)

In addition, for a Dirichlet edge \( e \in \mathcal{E}_D \), we set

\[
\mathcal{T}_{\mathcal{E}_{\ell, D}}^f [\eta] := \sum_{K \in \mathcal{E}_{\ell, D}^f} T^K_{e, D}[\eta], \quad \mathcal{T}_{\mathcal{E}_{\ell, D}}^f [\eta] := (h_K^2)^{-2} \eta \| \nabla \eta \|_{L^2(K)}^2.
\]

(5.26)

By property (5.18) there holds:

\[
\mathcal{T}_\mathcal{D}_\ell^f [\eta] \lesssim \mathcal{P}^8_{\text{DG}} (\mathcal{T}_\mathcal{D}_\ell^f [\eta^1] + \mathcal{T}_\mathcal{D}_\ell^f [\eta^2]), \quad \mathcal{T}_{\mathcal{E}_{\ell, \perp}}^f [\eta] \lesssim \mathcal{P}^8_{\text{DG}} (\mathcal{T}_{\mathcal{E}_{\ell, \perp}}^f [\eta^1] + \mathcal{T}_{\mathcal{E}_{\ell, \perp}}^f [\eta^2]),
\]

(5.27)

\[
\mathcal{T}_{\mathcal{E}_{\ell, D}}^f [\eta] \lesssim \mathcal{T}_{\mathcal{E}_{\ell, D}}^f [\eta^1] + \mathcal{T}_{\mathcal{E}_{\ell, D}}^f [\eta^2].
\]

Theorem 5.5. Let \( u \in N_{\perp}^2 (\Omega, C, E_D) \) be the solution of (1.1)-(1.3), and let \( u_{\text{DG}} \) be the DG approximation obtained from (4.2) with a sufficiently large penalty parameter \( \gamma > 0 \) in the dG space \( V_{\ell}^f \) in (3.10), respectively in \( V_{\ell}^f \) in (3.11), for a \( \sigma \)-geometric axiparallel mesh \( \mathcal{M}_\ell^f \). Let \( \eta = u - \Pi u \) with \( \Pi \) chosen in Section 5.1. Then for the approximation errors in (5.15), (5.16) there holds the error bound

\[
\| u - u_{\text{DG}} \|_{L^2} \leq C \mathcal{P}^2_{\text{DG}} (\mathcal{T}_\mathcal{D}_\ell^f [\eta^1] + \mathcal{T}_\mathcal{D}_\ell^f [\eta^2] + \sum_{e \in \mathcal{E}_\ell^f} (\mathcal{T}_{\mathcal{E}_{\ell, \perp}}^f [\eta^1] + \mathcal{T}_{\mathcal{E}_{\ell, \perp}}^f [\eta^2])
\]

(5.28)

\[
+ \sum_{e \in \mathcal{E}_\ell^f} (\mathcal{T}_{\mathcal{E}_{\ell, \perp}}^f [\eta^1] + \mathcal{T}_{\mathcal{E}_{\ell, \perp}}^f [\eta^2]).
\]

The constant \( C > 0 \) is independent of the refinement level \( \ell \), the local mesh sizes and the local polynomial degree vectors.

Proof. Starting from (5.20), the Galerkin orthogonality in Proposition 4.2, implies that \( a_{\text{DG}}(\xi, \eta) = -a_{\text{DG}}(\eta, \xi) \). Hence, by the coercivity of \( a_{\text{DG}} \) in Proposition 4.3, we arrive at

\[
\| \xi \|_{L^2} \lesssim -a_{\text{DG}}(\eta, \xi) =: T_1 + T_2,
\]

(5.29)

where

\[
T_1 = \sum_{K \in \mathcal{M}_\ell^f} \int_K \nabla h \eta \cdot \nabla h \xi \, dx + \theta \int_{\mathcal{F}_1 (\mathcal{M}) \cup \mathcal{F}_D (\mathcal{M})} \langle \nabla h \xi \rangle \cdot \| \eta \| \, ds + \gamma \int_{\mathcal{F}_1 (\mathcal{M}) \cup \mathcal{F}_D (\mathcal{M})} j [\eta] \cdot [\xi] \, ds,
\]

and

\[
T_2 = -\int_{\mathcal{F}_1 (\mathcal{M}) \cup \mathcal{F}_D (\mathcal{M})} \langle \nabla h \eta \rangle \cdot [\xi] \, ds.
\]
The first term is bounded using the Cauchy-Schwarz inequality:

\[
|T_1| \lesssim p_{\text{max}} \left( \| \nabla h \|_{L^2(\Omega)}^2 + \left\| h^{-1/2} \eta \right\|_{L^2(\mathcal{F}_1(\Omega) \cup \mathcal{F}_D(\Omega))}^2 \right)^{1/2} 
\times \left( \left\| \nabla \xi \right\|_{L^2(\Omega)}^2 + \left\| j^{-1/2} \left\| \nabla \xi \right\|_{L^2(\mathcal{F}_1(\Omega) \cup \mathcal{F}_D(\Omega))} \right\|_{L^2(\mathcal{F}_1(\Omega) \cup \mathcal{F}_D(\Omega))} \right)^{1/2}.
\]

Estimating the term involving \( \langle \nabla h \xi \rangle \) as in the proof of [10, Theorem 4.10], with the aid of [10, Lemma 4.3a)], we obtain

\[
|T_1| \lesssim p_{\text{max}} \left( \| \nabla h \|_{L^2(\Omega)}^2 + \left\| h^{-1/2} \eta \right\|_{L^2(\mathcal{F}_1(\Omega) \cup \mathcal{F}_D(\Omega))}^2 \right)^{1/2} \| \xi \|_{DG}. \tag{5.30}
\]

Next, we bound \( T_2 \): There holds

\[
|T_2| = \sum_{f \in \mathcal{F}_1(\Omega) \cup \mathcal{F}_D(\Omega)} \int_f \langle \nabla h \eta \rangle \cdot \mathbf{n}_f \| \xi \|_{DG} \| ds 
\lesssim \sum_{f \in \mathcal{F}_1(\Omega) \cup \mathcal{F}_D(\Omega)} \| j^{-1/2} \langle \nabla h \eta \rangle \cdot \mathbf{n}_f \|_{L^1(f)} \| j^{-1/2} \| \| \xi \| \|_{L^\infty(f)},
\]

where \( \mathbf{n}_f \) is an orthonormal vector on \( f \) pointing in a preset direction. Therefore, using [10, Lemma 4.3b)], it follows that

\[
|T_2| \lesssim p_{\text{max}}^2 \| \xi \|_{DG} \left( \sum_{f \in \mathcal{F}_1(\Omega) \cup \mathcal{F}_D(\Omega)} |f|^{-1/2} \| j^{-1/2} \langle \nabla h \eta \rangle \cdot \mathbf{n}_f \|_{L^1(f)} \| j^{-1/2} \| \| \xi \| \|_{L^2(f)} \right)^{1/2}
\lesssim p_{\text{max}}^2 \| \xi \|_{DG} \left( \sum_{f \in \mathcal{F}_1(\Omega) \cup \mathcal{F}_D(\Omega)} \sum_{K \in \mathcal{M} : f \in \mathcal{F}_1(\Omega) \cup \mathcal{F}_D(\Omega) \cap \mathcal{F}_K} |K|^{-1} \left( \| \nabla h \|_{L^2(\mathcal{F}_K)}^2 + (h^2_{K,f})^2 \| \nabla h \cdot \mathbf{n}_K \|_{L^2(f)}^2 \right) \right)^{1/2}.
\]

Since \( |\nabla \cdot \mathbf{n}_K| = |\partial_{K,f} \cdot \mathbf{n}_f| \) on \( f \in \mathcal{F}_K \), and \( |K| \approx |f| h^2_{K,f} \), applying the anisotropic trace inequality (4.5) with \( q = 1 \) yields

\[
|T_2| \lesssim p_{\text{max}}^2 \| \xi \|_{DG} \left( \sum_{K \in \mathcal{M} : f \in \mathcal{F}_1(\Omega) \cup \mathcal{F}_D(\Omega) \cap \mathcal{F}_K} \left( |K|^{-1} \| \nabla \eta \|_{L^2(\mathcal{F}_K)}^2 + (h^2_{K,f})^2 \| \nabla \cdot \mathbf{n}_K \|_{L^2(\mathcal{F}_K)}^2 \right) \right)^{1/2}.
\]

Using that \( \| \nabla \eta \|_{L^2(\mathcal{F}_K)} \leq |K|^{1/2} \| \nabla \eta \|_{L^2(f)} \) by Hölder’s inequality, we conclude that

\[
|K|^{-1} \| \nabla \eta \|_{L^2(f)}^2 \leq \| \nabla \eta \|_{L^2(\mathcal{F}_K)}^2.
\]

Since all elements \( K \) are axiparallel hexahedra, there are only two cases, \( f \parallel \mathbf{e} \) and \( f \perp \mathbf{e} \), where \( \mathbf{e} \) is the edge nearest to \( f \in \mathcal{F}_K \). In the former case, there holds \( (h^2_{K,f})^2 \| \partial_{K,f} \nabla \eta \|_{L^2(\mathcal{F}_K)}^2 = (h^2_{K,f})^2 \| \partial_{K,f} \eta \|_{L^2(\mathcal{F}_K)}^2 \) and in the latter \( (h^2_{K,f})^2 \| \partial_{K,f} \nabla \eta \|_{L^2(\mathcal{F}_K)}^2 = (h^2_{K,f})^2 \| \partial_{K,f} \eta \|_{L^2(\mathcal{F}_K)}^2 \). Therefore,

\[
|T_2| \lesssim p_{\text{max}}^2 \| \xi \|_{DG} \left( \sum_{K \in \mathcal{M}} \left( |K|^{-1} (h^2_{K,f})^2 \| \nabla \eta \|_{L^2(K)}^2 + |K|^{-1} (h^2_{K,f})^2 \| \nabla \eta \|_{L^2(K)}^2 \right) \right)^{1/2}.
\]
Combining this estimate with (5.29) and (5.30), dividing the resulting inequality by $\|\xi\|_{\text{DG}}$ and squaring results in

$$\|\xi\|_{\text{DG}}^2 \lesssim p_{\text{max}}^4 \left( \|\nabla_h \eta\|_{L^2(\Omega)}^2 + \sum_{f \in F_D \cup F_f} h_f^{-1} \|\eta\|_{L^2(f)}^2 \right)$$

$$+ \sum_{K \in M} |K|^{-1} \left( (h_K^2 \|D_1^2 \eta\|_{L^2(K)}^2) + (h_K^2 \|D_2^2 \eta\|_{L^2(K)}^2) \right).$$

Noticing that $\|u - u_{\text{DG}}\|_{\text{DG}}^2 \leq 2\|\eta\|_{\text{DG}}^2 + 2\|\xi\|_{\text{DG}}^2$, leads to

$$\|u - u_{\text{DG}}\|_{\text{DG}}^2 \lesssim p_{\text{max}}^4 \left( \|\nabla_h \eta\|_{L^2(\Omega)}^2 + \sum_{f \in F_D \cup F_f} h_f^{-1} \|\eta\|_{L^2(f)}^2 \right)$$

$$+ \sum_{K \in M} |K|^{-1} \left( (h_K^2 \|D_1^2 \eta\|_{L^2(K)}^2) + (h_K^2 \|D_2^2 \eta\|_{L^2(K)}^2) \right).$$

(5.31)

It remains to bound the jump of $\eta$. To this end, we distinguish several cases:

- If $f \perp e$ is an interior face perpendicular to the closest edge $e \in \mathcal{E}$, shared by two elements $K_1$ and $K_2$, with $h_f \approx h_{K_1} \approx h_{K_2} \approx h_{e}$, we use the trace estimate (4.5) with $q = 2$ to obtain

$$h_f^{-1} \|\eta\|_{L^2(f)}^2 \lesssim \sum_{i=1}^2 \left( h_{K_i}^2 |K_i|^{-1} \|\eta\|_{L^2(K_i)}^2 + \|\nabla \eta\|_{L^2(K_i)}^2 \right).$$

- For the jumps over interior anisotropic faces $f | e$ which are parallel to $e \in \mathcal{E}$ (and which are shared by two neighboring elements $K_1$ and $K_2$), we apply the anisotropic jump estimate in Proposition 5.4, and see that

$$h_f^{-1} \|\eta\|_{L^2(f)}^2 \lesssim \|D_\perp \eta\|_{L^2(K_1)}^2 + \|D_\perp \eta\|_{L^2(K_2)}^2$$

$$\lesssim \|\nabla \eta\|_{L^2(K_1)}^2 + |K|^{-1} \|\nabla \eta\|_{L^2(K_2)}^2.$$

- Finally, for jumps which abut at a Dirichlet boundary face, we apply the trace estimate (4.5) with $q = 2$ to obtain, for any $f \in F_D(M) \cap \mathcal{F}_K$,

$$h_f^{-1} \|\eta\|_{L^2(f)}^2 \lesssim (h_K^2)^{-1} \|\eta\|_{L^2(f)}^2 \lesssim (h_K^2)^{-1} \|\nabla \eta\|_{L^2(K_1)}^2$$

$$\lesssim (h_K^2)^{-1} \|\nabla \eta\|_{L^2(K)}^2.$$

Inserting these bounds into (5.31) results in

$$\|u - u_{\text{DG}}\|_{\text{DG}}^2 \lesssim p_{\text{max}}^4 \sum_{K \in M} \left( (h_K^2)^{-2} \|\eta\|_{L^2(K)}^2 + \|\nabla \eta\|_{L^2(K)}^2 \right)$$

$$+ \sum_{K \in M \setminus \mathcal{F}_e} |K|^{-1} (h_K^2 \|D_1^2 \eta\|_{L^2(K)}^2) + |K|^{-1} (h_K^2 \|D_2^2 \eta\|_{L^2(K)}^2)$$

$$+ \sum_{e \in F_D} \|\nabla \eta\|_{L^2(f)}^2 + \sum_{e \in \mathcal{E}} \mathcal{Y}_{\nabla, e} |\eta|.$$

For $K \in \mathcal{D}_e$ and for $K \in \mathcal{F}_e$, $e \in \mathcal{E}$, we estimate the $L^1(K)$-norms of $D_1^2 \eta$ and $D_2^2 \eta$ (the latter only for $K \in \mathcal{D}_e$) by their $L^2(K)$-norms using Hölder’s inequality. Moreover, noting that elements in $\mathcal{F}_e$ are isotropic with $h_K \approx h_K^2$ and $|K| \approx h_K^2$, yields

$$\|u - u_{\text{DG}}\|_{\text{DG}}^2 \lesssim p_{\text{max}}^4 \mathcal{Y}_{\mathcal{D}_e} |\eta| + p_{\text{max}}^4 \sum_{e \in \mathcal{E}} \left( \mathcal{Y}_{\nabla, e}^1 |\eta| + \mathcal{Y}_{\nabla, e}^2 |\eta| \right)$$

$$+ p_{\text{max}}^4 \sum_{e \in \mathcal{E}} \mathcal{Y}_{\nabla, e}^1 |\eta| + p_{\text{max}}^4 \sum_{K \in M \setminus \mathcal{F}_e} \|\nabla \eta\|_{L^2(K)}^2 + \sum_{e \in F_D} \mathcal{Y}_{\nabla, e} |\eta|.$$

Employing the splittings (5.27) and recalling that $\mathcal{M} = \mathcal{D}_e \cup \mathcal{F}_e \cup \mathcal{F}_e$ implies the assertion.
5.4. **Exponential convergence.** We are now ready to state the main result of this paper.

**Theorem 5.6.** Assume that the right-hand side $f$ of the boundary-value problem (1.1)–(1.3) in the axiparallel polyhedron $\Omega \subset \mathbb{R}^3$ belongs to the analytic space $B_{1-,b}(\Omega; C, E_D)$, with a weight vector $b$ satisfying (2.15) with $0 < b_C, b_h < 1$ as in Remark 2.4. Then the solution $u$ is in $B_{1-,b}(\Omega; C, E_D)$ according to Proposition 2.3.

Furthermore, let $\mathcal{M}_\sigma = \{M_{\sigma}^{(\ell)}\}_{\ell \geq 0}$ be a family of axiparallel $\sigma$-geometric meshes as introduced in Section 3.1, and consider the $hp$-dG discretizations in (4.2) based on the sequences of approximating subspaces $V^e_\sigma$ and $V^f_\sigma, s$ defined in (3.10) respectively (3.11), with the vector $p_1(M_{\sigma}^{(\ell)})$ in (3.10) of constant, isotropic and uniform polynomial degrees equal to $\ell$ for the space $V^e_\sigma$, respectively the $s$-linear, anisotropic degree distribution $p_2(M_{\sigma}^{(\ell)})$ for $V^f_\sigma, s$. All polynomial degrees are assumed greater than or equal to 3 in elements not abutting at edges $e$ or corners $c$.

Then for each $\ell \geq 0$, the $hp$-dG approximation $u_{DG}$ is well-defined, and as $\ell \to \infty$, the approximate solutions $u_{DG}$ satisfy the error estimate

$$\|u - u_{DG}\|_{DG} \leq C \exp \left(-b\sqrt{N}\right),$$

(5.32)

where $N = \dim\{V(M_{\sigma}^{(\ell)}, \Phi(M_{\sigma}^{(\ell)}), p(M_{\sigma}^{(\ell)}))\}$ denotes the number of degrees of freedom of the discretization for any of the two spaces $V^e_\sigma$ or $V^f_\sigma, s$.

The constants $b > 0$ and $C > 0$ are independent of $N$, but depend on $\sigma, M^0, \theta, \gamma$, $\min b > 0$, and on which of the polynomial degree vectors $p_1(M_{\sigma}^{(\ell)})$ or $p_2(M_{\sigma}^{(\ell)})$ are used.

**Remark 5.7.** In particular, the $hp$-dG interpolant constructed to prove Theorem 5.6 yields an exponential approximation bound of the discretization error in the dG norm as in (5.32) for any $u \in B_{1-,b}(\Omega)$.

The remainder of the paper is devoted to the proof of Theorem 5.6. To this end, we will construct appropriate $hp$-interpolants in Section 6 on interior, edge and corner elements. Furthermore, in Section 7 we show that the individual terms on the right-hand side of (5.28) all converge at an exponential rate. Finally, the proof of Theorem 5.6 will be completed in Section 7.6.

6. Approximation properties of $L^2$-projections

In this section, we establish some approximation results for $L^2$-projections as in (5.2), (5.3), for elements $K \in \Omega^e_\sigma$.

6.1. **One-dimensional projectors and $hp$-approximation results.** As in, e.g., [7, 9, 12], the ensuing exponential convergence proofs are based on projectors $\hat{\pi}_p$ onto polynomials of degree $p \geq 1$, with error bounds which are explicit in the polynomial degree and the regularity order $s$ on $\tilde{I} = (-1, 1)$.

**Lemma 6.1.** For any $3 \leq s \leq p$ and $u \in H^{s+1}(\tilde{I})$, we have

$$\|u - \hat{\pi}_p u\|^2_{H^s(\tilde{I})} \lesssim p^s \Psi_{p-1,s-1} \|u^{(s+1)}\|^2_{L^2(\tilde{I})}. 

(6.1)$$

**Proof.** From [4, Section 8], it follows that for every $p \geq 3$ there exists a projector $\hat{\pi}_{p,2} : H^2(\tilde{I}) \to P_{p}(\tilde{I})$ that satisfies $(\hat{\pi}_{p,2}u)^{(2)} = \hat{\pi}_{p-2}u^{(2)}$ and $(\hat{\pi}_{p,2})^{(1)}u(\pm 1) = u^{(1)}(\pm 1)$ for $j = 0, 1$. The projector $\hat{\pi}_{p,2}$ is stable in $H^2(\tilde{I})$. Moreover, for any $3 \leq s \leq p$ and $u \in H^{s+1}(\tilde{I})$, there holds the approximation bound

$$\|u - \hat{\pi}_{p,2} u\|^2_{H^s(\tilde{I})} \lesssim \Psi_{p-1,s-1} \|u^{(s+1)}\|^2_{L^2(\tilde{I})}. 

(6.2)$$

By the triangle inequality, the fact that $\hat{\pi}_p$ reproduces polynomials, and by the stability estimate (5.1), we see that

$$\|u - \hat{\pi}_p u\|_{H^s(\tilde{I})} \leq \|u - \hat{\pi}_{p,2} u\|_{H^s(\tilde{I})} + \|\hat{\pi}_p (u - \hat{\pi}_{p,2} u)\|_{H^s(\tilde{I})} \lesssim p^s \|u - \hat{\pi}_{p,2} u\|_{H^s(\tilde{I})}, 

(6.3)$$

Referring to (6.2) yields the assertion for any $u \in H^{s+1}(\tilde{I})$. \qed
In the remainder of this subsection, we establish exponential convergence results for a broken $hp$-interpolant on geometric meshes which will be used later, but which are also of independent interest. To that end, on $\omega = (0,1)$, we consider a sequence $\{T_{\sigma}^j\}_{j=1}^{\infty}$ of geometric meshes $T_{\sigma}^j = \{K_j\}_{j=1}^{\ell+1}$ with $\ell+1$ elements which are geometrically graded towards the origin with grading factor $0 < \sigma < 1$. The elements are given by $K_1 = (0,\sigma^j)$ and $K_j = (\sigma^{j+2}, \sigma^{j+1})$ for $2 \leq j \leq \ell + 1$. The size of element $K_j$ is given by

$$h_{K_j} = \sigma^{j+1-j}(1-\sigma), \quad 2 \leq j \leq \ell + 1,$$

which implies that there is a constant $\kappa$ solely depending on $\sigma$ such that

$$\kappa^{-1} h_{K_j} \leq |x| \leq \kappa h_{K_j}, \quad x \in K_j, \quad 2 \leq j \leq \ell + 1. \quad (6.5)$$

For a slope parameter $s > 0$, we define on $T_{\sigma}^j$ a $s$-linear polynomial degree vector $p$ of length $\ell+1$ given by $p_1 = (p_1, ..., p_{\ell+1})$, with $p_j = \max\{3, [sj]\}, j = 1, 2, ..., \ell + 1$, and set $|p| = \max_{j=1}^{\ell+1} p_j$.

We then consider the one-dimensional $hp$-version discontinuous finite element space

$$S^p,0(\omega; T_{\sigma}^j) = \{ u \in L^2(\omega) : u|_{K_j} \in \mathbb{P}^p(K_j), \ j = 1, 2, ..., \ell + 1 \}. \quad (6.6)$$

Then, we denote by $\pi_p$ the $L^2$-projection onto the space $S^p,0(\omega; T_{\sigma}^j)$, defined on each element $K_j$ as $\pi_p(u)|_{K_j} = \pi_p,0(u|_{K_j})$, with the elemental $L^2$-projection $\pi_p$ on $K_j$ as introduced in Section 5.1.1. For a function $u : \omega \to \mathbb{R}$, we define the approximation error by $\eta := u - \pi_p u$, and introduce the local error norm:

$$T_j[\eta] := h_{K_j}^{-2} \|\eta\|_{L^2(K_j)}^2 + \|\eta\|_{L^2(K_j)}^2 + h_{K_j}^2 \|\eta''\|_{L^2(K_j)}^2. \quad (6.7)$$

Proposition 6.2. For a weight $\beta > 0$, let $u : \omega \to \mathbb{R}$ be such that

$$\|x|^{1-\beta+s} u(x)\|_{L^2(\omega)} \leq C_s^{\alpha+1} \Gamma(s + 1), \quad s \geq 2. \quad (6.8)$$

Then for $\ell$ sufficiently large, we have $\sum_{j=2}^{\ell+1} T_j[\eta] \leq C \exp(-2b\ell)$, with constants $b, C > 0$ which are independent of $\ell$.

Proof. Fix an element $K_j \in T_{\sigma}^j$ for $2 \leq j \leq \ell + 1$. A straightforward scaling argument yields

$$T_j[\eta] \approx \left( \frac{h_{K_j}}{2} \right)^{-1} \|\eta\|_{H^2(\widehat{K})}^2,$$

where as usual we denote by $\widehat{K}$ the pullback of $\eta|_{K_j}$ to the reference interval $\widehat{I} = (-1,1)$. Therefore the approximation bound (6.1) implies that

$$T_j[\eta] \lesssim |p|^s \left( \frac{h_{K_j}}{2} \right)^{-1} \Psi_{p_j-1, s_j-1} \|\hat{u}(s_j+1)\|^2_{L^2(\widehat{K})},$$

for any $3 \leq s_j \leq p_j$. Scaling the right-hand side above back to element $K_j$ results in

$$T_j[\eta] \lesssim |p|^s \left( \frac{h_{K_j}}{2} \right)^{2s_j} \Psi_{p_j-1, s_j-1} \|u(s_j+1)\|^2_{L^2(K_j)}. \quad (6.9)$$

Moreover, by the equivalence (6.5),

$$\|u(s_j+1)\|^2_{L^2(K_j)} \simeq h_{K_j}^{2+2\beta-2(s_j+1)} \|x|^{-1-\beta+(s_j+1)} u(s_j+1)\|^2_{L^2(K_j)}. \quad (6.10)$$

By combining (6.9), (10) with (6.8), we find that

$$T_j[\eta] \lesssim |p|^s \frac{h_{K_j}^{2\beta}}{2^{2s_j}} \Psi_{p_j-1, s_j-1} \|x|^{-1-\beta+(s_j+1)} u(s_j+1)\|^2_{L^2(K_j)}$$

$$\lesssim |p|^s \frac{h_{K_j}^{2\beta}}{2^{2s_j}} \Psi_{p_j-1, s_j-1} \Gamma(s_j + 2)^2, \quad (6.11)$$

for any integer index $3 \leq s_j \leq p_j$. An interpolation argument as in [11, Lemma 5.8] shows that the bound (6.11) holds for any real $s_j \in [3, p_j]$. 

Next, we sum the bound (6.11) over all layers $2 \leq j \leq \ell + 1$. In view of (6.4), we obtain

$$\sum_{j=2}^{\ell+1} T_j[\eta] \lesssim |p|^8 \left( \sum_{j=2}^{\ell+1} \sigma_{2(\ell+1-j)^\beta} \min_{s_j \in [3,p]} \left[ C^{2s_j} \Psi_{p_{j-1},s_{j-1}} \Gamma(s_j + 2) \right] \right).$$

In [11, Lemma 5.12], it has been shown that terms of the form as in the bracket on the right-hand side above can be bounded by $C \exp(-2b(\ell + 1))$. By possibly increasing the constant $C > 0$ and by reducing the value of $b$, the algebraic factor $|p|^8$ can be absorbed into the exponential convergence bound.

Similarly, we obtain the following result.

**Proposition 6.3.** For a weight exponent $\beta > 0$, let $u : \omega \to \mathbb{R}$ be such that there exists a constant $C_u > 0$ with

$$\| |x|^{-\beta + s} u(s) \|_{L^2(\omega)} \leq C_u |s + 2| \quad \forall s \geq 2. \quad (6.12)$$

Then there exist constants $b, C > 0$ such that, for every $\ell \geq 2$, we have $\sum_{j=2}^{\ell+1} \| \eta \|^2_{L^2(K_j)} \leq C \exp(-2b\ell)$, with constants $b, C > 0$ which are independent of $\ell$.

**Proof.** We may assume that $\ell$ is sufficiently large. Fix an element $K_j \in T^e_\ell$ for $2 \leq j \leq \ell + 1$. Scaling gives $\| \eta \|^2_{L^2(K_j)} = h_{K_j}/z(\| \eta \|^2_{L^2(\tilde{K}_j)})$. Then, the approximation bound (6.1), a scaling argument, the equivalence (6.5), and the regularity assumption (6.12) yield, for $3 \leq s_j \leq p_j$,

$$\| \eta \|^2_{L^2(K_j)} \lesssim |p|^8 \left( \frac{h_{K_j}}{2} \right)^{2s_j + 2} \| \Psi_{p_{j-1},s_{j-1}} \|^2_{L^2(K_j)} \lesssim |p|^8 \left( \frac{h_{K_j}}{2} \right)^{2s_j + 2} \| \eta \|^2_{L^2(K_j)} \lesssim |p|^8 \left( \frac{h_{K_j}}{2} \right)^{2s_j + 2} \| \eta \|^2_{L^2(K_j)} \lesssim |p|^8 \left( \frac{h_{K_j}}{2} \right)^{2s_j + 2} \| \eta \|^2_{L^2(K_j)}.$$

From here, the desired estimate follows as in the proof of Proposition 6.2.

---

**6.2. Approximation properties of $L^2$-projection on axiparallel hexahedra.** Now we provide approximation properties of the element-average projection (5.2), (5.3). In the setting (5.15), (5.16), we first show the following estimate for $\eta^\perp$.

**Lemma 6.4.** Let $K$ be an axiparallel hexahedron. For $0 \leq |\alpha^\perp|$, $0 \leq \alpha \leq 2$, and $3 \leq s_K \leq p_K$, there holds

$$\| \tilde{D}_\perp^{\alpha^\perp} \tilde{D}_\perp^{\alpha} \tilde{\eta} \|^2_{L^2(K)} \lesssim (p_K)^8 \left( \frac{1}{p_{K-1}^\perp} \left( h_{K-1} \right)^{2|\alpha^\perp| - 2} \left( h_K \right)^{|\alpha|} \right) \| D_\perp^{\alpha^\perp} D_\perp^{\alpha} \eta \|^2_{L^2(K)}. \quad (6.13)$$

**Proof.** Note that $\tilde{D}_\perp^{\alpha^\perp} \tilde{D}_\perp^{\alpha} \tilde{\eta} = \tilde{D}_\perp^{\alpha^\perp} \left( (\tilde{D}_\perp^{\alpha^\perp} \tilde{u}) - \tilde{D}_\perp^{\alpha^\perp} \tilde{\eta} \right)$. Applying Lemma 6.1 in edge-parallel direction, we obtain $\| \tilde{D}_\perp^{\alpha^\perp} \tilde{D}_\perp^{\alpha} \tilde{\eta} \|^2_{L^2(\tilde{K})} \lesssim (p_K)^4 \frac{1}{p_{K-1}^\perp} \| \tilde{D}_\perp^{\alpha^\perp} \tilde{D}_\perp^{\alpha} \tilde{\eta} \|^2_{L^2(\tilde{K})}$. A scaling argument as in [11, Section 5.1.4] implies the bound (6.13).

Second, we derive the following bound for $\eta^\perp$. To that end, we introduce the tensor-product space $H_{mix}^2(\tilde{K}) := H^2(\tilde{I}) \otimes H^2(\tilde{I}) \otimes H^2(\tilde{I})$, and endow it with the standard tensor-product norm.

**Lemma 6.5.** For an axiparallel element $K$ and $3 \leq s_K \leq p_K$, there holds

$$\| \eta^\perp \|^2_{H_{mix}^2(K)} \lesssim (p_K)^{10} E_{p_{K-1}^\perp}^\perp (K), \quad (6.14)$$

with

$$E_{p_{K-1}^\perp}^\perp (K) = \Psi_{p_{K-1}^\perp, s_K-1} \sum_{s_{\alpha^\perp} \in 2 \mathbb{Z}, s_{\alpha^\perp} \leq s_K-1} \left( h_{K-1} \right)^{2|\alpha^\perp| - 2} \left( h_K \right)^{|\alpha| - 1} \| D_\perp^{\alpha^\perp} D_\perp^{\alpha} \eta \|^2_{L^2(K)}. \quad (6.15)$$
Prove. In view of (5.2), (5.3), we may write
\[ \tilde{\eta}^\perp = \tilde{\eta} - \tilde{\eta}^{(1)}_{p_K} \otimes \tilde{\eta}^{(2)}_{p_K} = (\tilde{\eta} - \tilde{\eta}^{(1)}_{p_K} \otimes \tilde{\eta}^{(2)}_{p_K}) + \tilde{\eta}^{(1)}_{p_K} (\tilde{\eta} - \tilde{\eta}^{(2)}_{p_K}) \cdot \]
Hence, by the triangle inequality and the stability properties in (5.1), we readily find that
\[ \| \tilde{\eta}^\perp \|^2_{H_0^2(K)} \lesssim (p_{p_K}^\perp)^8 \left( \sum_{\ell=1}^2 \| \tilde{\eta} - \tilde{\eta}^{(1)}_{p_K} \|_{H_0^2(K)}^2 \right). \]
Lemma 6.1 (used in directions \( x_1 \) and \( x_2 \)) now implies
\[ \| \tilde{\eta}^\perp \|^2_{H_0^2(K)} \lesssim (p_{p_K}^\perp)^{16} \Psi_{p_{p_K}^\perp -1, s_{p_K}^\perp -1} \left( \sum_{0 \leq \alpha^2, \alpha^1 \leq 2} \| \tilde{\eta} (s_{p_K}^\perp + 1, \alpha^1) \|_{L^2(K)}^2 \right) + \sum_{0 \leq \alpha^1, \alpha^1 \leq 2} \| \tilde{\eta} (\alpha^1, s_{p_K}^\perp + 1, \alpha^1) \|_{L^2(K)}^2. \]
This bound and a scaling argument as in [11, Section 5.1.4] yield the desired bound.

Remark 6.6. It is worth pointing out that a tensor-product argument similar to that in the proof of Lemma 6.5 (see also [11, Section 5.2.1]) applied to the tensor-product projector \( \Pi_{p_K} \) in (5.2) implies the following bound: for any axiparallel element \( K \) and for \( \eta = u - \Pi_{p_K} u \), there holds
\[ \| \tilde{\eta} \|^2_{H_0^2(K)} \lesssim |p_{p_K}|^{16} \left( E_{p_{p_K}^\perp, s_{p_K}^\perp} (K) + E_{p_{p_K}^\perp, s_{p_K}^\perp} (K) \right), \]
for any \( 3 \leq s_{p_K}^\perp \leq p_{p_K}^\perp \) and \( 3 \leq s_{p_K}^\perp \leq p_{p_K}^\perp \) with
\[ E_{p_{p_K}^\perp, s_{p_K}^\perp} (K) = \Psi_{p_{p_K}^\perp -1, s_{p_K}^\perp -1} \left( \sum_{0 \leq \alpha^2, \alpha^1 \leq 2} (h_{p_K}^\perp)^{2 \alpha^1 - 2} (h_{p_K}^\perp)^{2 s_{p_K}^\perp + 1} \| D^{\alpha^1}_{\|} D^{s_{p_K}^\perp + 1}_{\|} u \|_{L^2(K)}^2 \right), \]
and \( E_{p_{p_K}^\perp, s_{p_K}^\perp} (K) \) defined in (6.15). Up to the algebraic loss in \( |p_{p_K}| \), the estimate (6.16) is the same as that in [11, Lemma 5.6] used in the analysis of the pure Dirichlet case. However, in the case of a corner-edge patch involving a Neumann edge, we shall invoke the finer bound in Lemma 6.4.

7. Reference corner-edge patch

According to the construction of the hp-dG spaces provided in Section 3, the geometric edge mesh \( \mathcal{M}^\ell \) consists of a finite number of physical patches \( \{ \mathcal{M}^\ell_j \}_{j=1} \). This makes it possible to bound the right-hand side of (5.28) separately on each \( \mathcal{M}^\ell_j \) by means of a suitable hp-approximation analysis. In addition, noting that each patch \( \mathcal{M}^\ell_j \) is equivalent (up to isotropic dilation, translation and/or rotation) to one of the reference patches displayed in Figure 1, it is sufficient to limit the proof of the exponential convergence bounds to the reference situations from Figure 1. Indeed, due to the simple structure of the patch mappings, the weighted Sobolev space \( \mathcal{N}^\ell_2 (\mathcal{M}^\ell_j; \mathcal{C}, \mathcal{E}_D) \), as restricted to a physical patch \( \mathcal{M}^\ell_j \), can be identified with an equivalent space, which features the same regularity and is equipped with equivalent norms, on one of the reference patches.

7.1. The setting. We consider a reference corner-edge patch in \((0, 1)^3\) consisting of a single corner \( c \in \mathcal{C} \) and a single edge \( e \in \mathcal{E}_e \) originating from it; see Figure 1 (right) for an illustration. We may assume that \( c = (0, 0) \) and \( e = \{0\} \times \omega_e^\ell \) with \( \omega_e^\ell = (0, 1) \).

Similarly to [11], we now introduce a reference geometric corner-edge mesh \( \widehat{\mathcal{M}}^\ell_{ce} \). As in [11], \( \widehat{\mathcal{M}}^\ell_{ce} \) is built from mesh layers via
\[ \widehat{\mathcal{M}}^\ell_{ce} = \bigcup_{j=1}^{\ell+1} \bigcup_{j=1}^{\ell+1} \widehat{\mathcal{L}}^{ij}_{ce}, \]
where the sets \( \widehat{\mathcal{L}}^{ij}_{ce} \) stand for layers of elements with identical scaling properties. The decomposition in (7.1) is not a partition, in general: elements may be contained in several layers whose number, however, is uniformly bounded with respect to \( \ell \).
We note that our hp distributions on \( \hat{K} \) that is given by \( \omega \) along the edge \( \hat{\omega} \). Finally, any element in the layer \( \hat{\omega} \) is isotropic with \( r_{e|K} \simeq d_{e|K} \leq h_{e|K} \simeq \sigma^\ell \). The cardinality of the layers \( \hat{\omega} \) depends on the implied equivalence constants in (7.4)–(7.6). We emphasize that the ensuing analysis is valid for any choice of these constants (independent of \( i, j, \ell \)). For the reference patch as shown in Figure 1 (right) the sets \( \hat{\omega} \) are in fact singletons, and any \( K \in \hat{\omega} \) can be written in the form

\[
K_j = K^\perp \times K^\parallel, \quad 2 \leq j \leq \ell + 1,
\]

where \( K^\perp = (0, \sigma^\ell)^2 \), and the sequence \( \{K^\parallel\}^\ell_{i=2} \) forms a one-dimensional geometric mesh \( T^\ell_\alpha \) along the edge \( \omega^\parallel = (0, 1) \) as in Section 6.1; moreover, there is a single corner element \( K \in \hat{T}_\alpha \) that is given by \( K = (0, \sigma^\ell)^3 \).

In agreement with the reference corner-edge patch \( \hat{\omega} \), and the reference edge patch \( \hat{\omega} \), which correspond to the rightmost display in Fig. 1, we consider a-linear polynomial degree distributions on \( \hat{\omega} \) that satisfy

\[
\forall K \in \hat{\omega} : \quad p_K = (p_1^+, p_2^+) \simeq (\max\{[si], 3\}, \max\{[sj], 3\}), \quad 1 \leq i \leq j \leq \ell + 1.
\]

We note that our hp-approximation analysis below allows for max \( p_K < 3 \) in corner elements \( K \in \hat{T}_\alpha \).

Let now \( \hat{\Omega}^\ell_\alpha \) denote the domain formed by all elements in \( \hat{\omega} \):

\[
\hat{\Omega}^\ell_\alpha = \left( \bigcup_{K \in \hat{\omega}} \hat{\mathcal{K}} \right)^\circ.
\]

Analogous to the reference corner-edge patch \( \hat{\omega} \), corresponding to the rightmost display in Fig. 1, we introduce the reference corner patch \( \hat{\omega} \), and the reference edge patch \( \hat{\omega} \), which correspond to the leftmost and the middle panel, respectively, in Fig. 1. For the purpose of deriving the ensuing exponential convergence estimates it is important that the corresponding geometric mesh patches can be characterized as collections of certain elements \( K \in \hat{\omega} \): for \( \ell \geq 2 \), we define with \( \hat{\omega} \) as in (7.1)

\[
\forall e \in C : \quad \hat{M}_c^\ell = \hat{\mathcal{D}}_c^\ell \cup \hat{\mathcal{L}}_c^\ell, \quad \hat{\mathcal{D}}_c^\ell := \bigcup_{j=2}^{\ell+1} \hat{\mathcal{D}}_{c|j}^\ell, \quad \hat{\mathcal{L}}_c^\ell := \hat{\mathcal{L}}_{c|\ell}^\ell.
\]

\[
\forall e \in E : \quad \hat{M}_e^\ell = \hat{\mathcal{D}}_e^\ell \cup \hat{\mathcal{L}}_e^\ell, \quad \hat{\mathcal{D}}_e^\ell := \bigcup_{j=2}^{\ell+1} \hat{\mathcal{D}}_{e|j}^\ell, \quad \hat{\mathcal{L}}_e^\ell := \hat{\mathcal{L}}_{e|\ell}^\ell.
\]

We establish exponential convergence of the hp-dGFEM by proving exponential convergence estimates for the consistency bound (5.28) for each of the three canonical geometric mesh patches.
shown in Fig. 1. We remark that we abuse notation slightly in that the definition of \( \hat{\Sigma}_e \) and \( \hat{\Sigma}_{e_{\text{ce}}} \) in (7.10) and (7.11) differs from (7.3); it will be clear from the case discussed which definition is applicable. Due to (7.10) and (7.11), the required exponential convergence bounds for each of the three basic geometric mesh patches depicted in Fig. 1 will follow from consistency error estimates in patch \( \hat{\Omega}^e_{ce} \) which we therefore now consider next.

For a function \( u : \hat{\Omega}^e_{ce} \rightarrow \mathbb{R} \) (whose regularity will be specified below) and for \( K \in \hat{\mathcal{M}}^e_{ce} \), we define the elemental approximation operators \((\Pi K)u = \Pi_K u|_K \) in accordance with the choices in Section 5.1. That is, for interior elements \( K \in \hat{\Sigma}^e \) we select \( \Pi_K \) to be the \( L^2 \)-projection as in (5.2), (5.3), with the elemental polynomial degrees taken as \( p^\perp = p^\perp_i, p^K = p^K_j \); cp. (7.8). For \( K \in \hat{\Sigma}^e_{e_{\text{ce}}} \), we select \( \Pi_K \) as in (5.11) with \( p^K_{i_j} = p^K_j \). Finally, for the corner element \( K \in \hat{\Sigma}^e_{e_{\text{ce}}} \), we select \( \Pi_K \) in agreement with (5.12). For functions \( u : \hat{\Omega}^e_{ce} \rightarrow \mathbb{R} \) and \( u : \hat{\Omega}^e_{ce} \rightarrow \mathbb{R} \), we will obtain exponential convergence estimates as direct consequences from the elementwise bounds established in the analysis on \( \hat{\Omega}^e_{ce} \rightarrow \mathbb{R} \).

For the dG approximation errors \( \eta, \eta^\perp, \eta \) as in (5.15), (5.16), and in view of the error estimates in Theorem 5.5, we will now bound the contributions \( \Upsilon_{\hat{\Omega}^e_{ce}} \), \( \Upsilon_{\hat{\Omega}^e_{ce}^{\perp}} \), \( \Upsilon_{\hat{\Omega}^e_{ce}}^{\perp} \), and \( \Upsilon_{\hat{\Omega}^e_{ce}}^{\perp} \), where these terms are defined exactly as in (5.21)–(5.25). If \( e \) is a Dirichlet edge, we shall also estimate \( \Upsilon_{\hat{\Omega}^e_{ce,D}} \) given as in (5.26).

### 7.2. Exponential Convergence at Neumann Edges

We shall first consider the case where \( e \in \mathcal{E}_c \) is a Neumann edge, i.e., \( e \in \mathcal{E}_N \). By the regularity property (2.16), the definition of the weighted seminorm (2.11) in the neighbourhood of Neumann edges, and for exponents \( b_c, b_e \in (0, 1) \) as in (2.15) and Remark 2.4, the solution \( u \) localized in \( \hat{\Omega}^e_{ce} \) has finite corner-edge seminorm (obtained by localization of (2.11) to \( \hat{\Omega}^e_{ce} \))

\[
|u|^2_{\hat{N}_{-1-b}^h(\hat{\Omega}^e_{ce})} = \sum_{|\alpha| = k} \left\| r_{e}^{-1-b_c+|\alpha|} p^{|-1-b_c+|\alpha|+0}_e \| \right\|_{L^2(\hat{\Omega}^e_{ce})}^2, \quad k > k_{\beta},
\]

with \( k_{\beta} \) in (2.12). Under the assumptions on the weights \( b_c, b_e \) in Remark 2.4, we note that, for \( \alpha \parallel \geq 0 \), the seminorms on the right-hand side of (7.12) take the following forms:

\[
\left\{ \begin{array}{ll}
\left\| r_{e}^{-1-b_c+\alpha} D^\alpha u \right\|_{L^2(\hat{\Omega}^e_{ce})}^2, & |\alpha| = 0, \\
\left\| r_{e}^{-1-b_c+\alpha} D^\alpha u \right\|_{L^2(\hat{\Omega}^e_{ce})}^2, & |\alpha| = 1, \\
\sum_{|\alpha| = k} \left\| r_{e}^{-1-b_c+\alpha} D^\alpha u \right\|_{L^2(\hat{\Omega}^e_{ce})}^2, & k \geq |\alpha| \geq 2.
\end{array} \right.
\]

The corresponding norms \( \| \cdot \|_{\hat{N}^m_{-1-b}^h(\hat{\Omega}^e_{ce})} \) and the weighted spaces \( \hat{N}^m_{-1-b}^h(\hat{\Omega}^e_{ce}) \) are then defined as in Section 2.2, for \( m > k_{\beta} \). For elements \( K \in \hat{\Omega}^e_{ce} \) we denote by \( | \cdot |_{\hat{N}^m_{-1-b}^h(K)} \) the restriction of the norm in (7.12) to \( K \), and similarly for the full norm. We say a function \( u \in H^1(\hat{\Omega}^e_{ce}) \) belongs to \( B_{-1-b}^h(\hat{\Omega}^e_{ce}) \) if \( u \in \hat{N}^k_{-1-b}(\hat{\Omega}^e_{ce}) \) for \( k > k_{\beta} \) and there is a constant \( d_u > 0 \) such that

\[
\| u \|_{\hat{N}^k_{-1-b}(\hat{\Omega}^e_{ce})} \leq d_u k_{\beta}! , \quad k > k_{\beta}.
\]

In the corner patch \( \hat{\Omega}^e_{ce} \) and the reference edge patch \( \hat{\Omega}^e_{ce} \) defined in (7.10) and (7.11), respectively, expressions analogous (but simpler) to (7.12) for the respective seminorms result: since \( p_{ce} |\hat{\Omega}^e_{ce} = O(1) \),

\[
|u|^2_{\hat{N}_{-1-b}^h(\hat{\Omega}^e_{ce})} = \sum_{|\alpha| = k} \left\| r_{e}^{-1-b_c+|\alpha|} D^\alpha u \right\|_{L^2(\hat{\Omega}^e_{ce})}^2
\]

(note that in \( \hat{\Omega}^e_{ce} \) the weights are homogeneous as in the Dirichlet case considered in [11]), and in the reference Neumann edge-patch \( \hat{\Omega}^e_{ce} \), we have

\[
|u|^2_{\hat{N}_{-1-b}^h(\hat{\Omega}^e_{ce})} = \sum_{|\alpha| = k} \left\| r_{e}^{-1-b_c+|\alpha|+0} D^\alpha u \right\|_{L^2(\hat{\Omega}^e_{ce})}^2.
\]
Then we invoke this equivalence and the analytic regularity (7.14) to obtain that there exists a
Proposition 7.3. According to (7.3), we consider
reference cube
exponential convergence of \( \Upsilon \)
one reference corner-edge patch \( \bar{D}_{ce} \). The general result will then follow upon noting that \( \bar{D}_{ce} \) is obtained by a finite superposition of (scaled and translated versions of) this reference corner-edge patch.

**Theorem 7.1.** Let \( \mathfrak{e} \in \mathcal{E}_N \) be a Neumann edge. Let \( u \in B_{-1-b}(\bar{D}_{ce}) \) as in (7.12), (7.14), and let \( \Pi_K \) denote the elemental approximation operators chosen as in Section 5.1. Then for \( \eta, \eta^- \), \( \eta^- \) as in (5.15), (5.16), there exist constants \( b, C > 0 \) such that, for \( \ell \) sufficiently large, there holds the exponential convergence estimate

\[
Y_{\bar{D}_{ce}}[\eta^+] + Y_{\bar{D}_{ce}}[\eta^-] + Y_{\bar{D}_{ce}}[\eta^+] + Y_{\bar{D}_{ce}}[\eta^-] + Y_{\bar{D}_{ce}}[\eta^-] \leq C \exp(-2b\ell). \tag{7.17}
\]

Analogous exponential convergence bounds hold for the consistency terms from \( \bar{D}_{ce}^\ell, \bar{D}_{ce}^\ell \).

The proof of the exponential convergence bound (7.17) in Theorem 7.1 will be presented in several steps. The proofs for the bounds on the terms \( \bar{D}_{ce}^\ell, \bar{D}_{ce}^\ell \) are analogous (by choosing \( h_K = O(1) \) in the proofs which follow) and will not be detailed.

3.1. Exponential convergence of \( Y_{\bar{D}_{ce}} \). For \( \mathfrak{e} \in \mathcal{E}_N \) and for \( u \in B_{-1-b}(\bar{D}_{ce}) \), we prove exponential convergence of \( Y_{\bar{D}_{ce}}[\eta^+] \) and \( Y_{\bar{D}_{ce}}[\eta^-] \) in (7.17). We begin by recording scalings to the
reference cube \( \bar{K} = (-1,1)^3 \) of the terms contained in \( T_{\bar{D}}^K[v] \) in (5.22).

**Lemma 7.2.** For \( K \in \bar{D}_{ce} \) and for \( v \in H^2(K) \), there holds:

\[
(h_K)^{-2}\|v\|_{L^2(K)}^2 + \|D_1^h v\|_{L^2(K)}^2 + (h_K)^2 \|D_2^h v\|_{L^2(K)}^2 \lesssim (h_K)^2 (h_K)^{-1} \left( \sum_{0 \leq \alpha \leq 2} \|\hat{\nabla}_v^\alpha \hat{\nabla}_v^\alpha \|_{L^2(K)}^2 \right), \tag{7.18}
\]

as well as

\[
(h_K)^{2(\alpha^+ - 1)} \|D_1^h v\|_{L^2(K)}^2 \lesssim h_K \|\hat{\nabla}^{\alpha^+} \hat{\nabla}_v^\alpha \|_{L^2(K)}^2, \quad |\alpha^+| = 1.2. \tag{7.19}
\]

**Proof.** These inequalities are an immediate consequence of the scalings in [11, Section 5.1.4].

Next, we bound the error term \( Y_{\bar{D}_{ce}}[\eta^+] \) in direction perpendicular to edge \( e \).

**Proposition 7.3.** Let \( u \in B_{-1-b}(\bar{D}_{ce}) \) as in (7.12), (7.14). Then there exist constants \( b, C > 0 \) such that for \( \ell \geq 2 \) holds \( Y_{\bar{D}_{ce}}[\eta^+] \leq C \exp(-2b\ell) \).

**Proof.** According to (7.3), we consider \( K \in \bar{D}_{ce} \) with \( 2 \leq j \leq \ell + 1 \) and \( 2 \leq i \leq j \). The scalings in (7.18), (7.19) and the fact that in \( \bar{D}_{ce}^\ell \) holds \( h_K \leq h_K^\ell \) allow us to conclude that

\[
T_{\bar{D}}^K[\eta^+] \lesssim (h_K)^2 (h_K)^{-1} + (h_K^\ell)^2 \|\hat{\nabla}^\alpha \|_{H^{\text{mix}}(K)}^2 = h_K \left( 1 + (h_K)^2 (h_K)^{-2} \right) \|\hat{\nabla}^\alpha \|_{H^{\text{mix}}(K)}^2 \lesssim h_K \|\hat{\nabla}^\alpha \|_{H^{\text{mix}}(K)}^2.
\]

With Lemma 6.5 and (7.8), we obtain

\[
T_{\bar{D}}^K[\eta^+] \lesssim |K|^{10} \|h_K^\ell \Psi_{p_K+1} - 1, s^+ - 1 \sum_{0 \leq \alpha^- \leq 2} (h_K)^{2(\alpha^+ - 2)} (h_K^{2\alpha^- - 2\alpha^-}) \|D_1^\alpha D_1^\alpha \|_{L^2(K)}^2.
\]

Since \( K \in \bar{D}_{ce}^\ell \) with \( 2 \leq j \leq \ell + 1 \) and \( 2 \leq i \leq j \), there hold the equivalences (7.5) on \( K \), and we may insert the appropriate weights according to (7.13) to obtain

\[
\|D_1^\alpha D_1^\alpha \|_{L^2(K)}^2 \sim (c_K^{2\alpha^- 2\alpha^-}) (c_K^{2\alpha^- 2\alpha^-}) \|D_1^{\alpha^-} + n \|_{L^2(K)}^2 \|D_1^\alpha D_1^\alpha \|_{L^2(K)}^2.
\]

Then we invoke this equivalence and the analytic regularity (7.14) to obtain that there exists a constant \( C > 0 \) such that for all \( p_K, r^+ \) and \( s^+ \) holds

\[
T_{\bar{D}}^K[\eta^+] \lesssim |K|^{10} \Psi_{p_K+1} - 1, s^+ - 1 (d_K^{2\alpha^- 2\alpha^-}) (d_K^{2\alpha^- 2\alpha^-}) \Gamma(s^+ + 6)^2. \tag{7.20}
\]
Summing (7.20) over all layers in $\mathcal{D}_e$ in (7.3) with the use of (7.5) results in
\[ \mathcal{T}_{\mathcal{D}_e} [\eta^\perp] \lesssim p_{\text{max}}^{16} \sum_{j=2}^{l+1} \sigma^{2(b_c-b_e)(l+1-j)} \sum_{i=2}^{j} \sigma^{2b_c(l+1-i)} \Psi_{p_i^+,s^+_i-1} \Gamma(s_i^+ + 6)^2. \]

By interpolating to real parameters $s_i^+ \in [3, p_i^+]$ as in [11, Lemma 5.8], this sum is of exactly the same form as $S_+^3$ in the proof of [11, Proposition 5.17], and the assertion now follows from the arguments there and after possibly adjusting the constants to absorb the algebraic loss in $p_{\text{max}}$.

To establish the analog of Proposition 7.3 in edge-parallel direction, we make use of the following estimates.

**Lemma 7.4.** Let $K \in \mathcal{D}_e$, and $3 \leq s_K \leq p_K^+$. Then there holds
\[ (h_K^2)^{-2} \| \eta \|_{l^2(K)}^2 + \| D_+ \eta \|_{l^2(K)}^2 + (h_K^2)^2 \| D^2_+ \eta \|_{l^2(K)}^2 \lesssim \left( \frac{p_K}{p_K^+} \right)^8 \Psi_{p_K^+,s_K^+-1} (d_K^e)^{2b_e} \| u \|^2_{N_{s_K^+-1}(K)}. \]

(7.21)

\[ \| D_\perp \eta \|_{l^2(K)}^2 \lesssim \left( \frac{p_K}{p_K^+} \right)^8 \Psi_{p_K^+,s_K^+-1} (d_K^e)^{2b_e} \| u \|^2_{N_{s_K^+-1}(K)}. \]

(7.22)

as well as
\[ (h_K^2)^2 \| D^2_\perp \eta \|_{l^2(K)}^2 \lesssim \left( \frac{p_K}{p_K^+} \right)^8 \Psi_{p_K^+,s_K^+-1} (d_K^e)^{2b_e} \| u \|^2_{N_{s_K^+-1}(K)} \cdot (d_K^e)^{2b_e} \| u \|^2_{N_{s_K^+-1}(K)}. \]

(7.23)

**Proof.** We prove (7.21) by bounding the right-hand side in (7.18) with the aid of the approximation property (6.13) (with $|\alpha^\perp| = 0$):
\[ (h_K^2)^{-2} \| \eta \|_{l^2(K)}^2 + \| D_+ \eta \|_{l^2(K)}^2 + (h_K^2)^2 \| D^2_+ \eta \|_{l^2(K)}^2 \lesssim (h_K^2)^2 \left( \sum_{0 \leq \alpha^\perp \leq 2} \| \tilde{D}_\perp^{s_\alpha^\perp} \|_{l^2(K)}^2 \right) \lesssim \left( \frac{p_K}{p_K^+} \right)^8 \Psi_{p_K^+,s_K^+-1} (h_K^2)^{2s_K} \| D_\perp^{s_K+1} \|_{l^2(K)}^2. \]

Then, we insert the weight $r_e$ by the use of (7.13), (7.4). We find that
\[ \| D^{s_K+1} u \|_{l^2(K)}^2 \sim (d_K^e)^{2s_K+2b_e} \| r_{e^{-1}} \|_{l^2(K)}^2 \| D_\perp^{s_K+1} \|_{l^2(K)}^2 \lesssim (d_K^e)^{2s_K+2} \| u \|^2_{N_{s_K^+-1}(K)}. \]

Combining the two estimates above shows (7.21).

To establish (7.22), we start from the the right-hand side of (7.19), apply (6.13) (with $|\alpha^\perp| = 1$ and $\alpha^\parallel = 0$), and insert the appropriate weights employing (7.4). This results in
\[ \| D_\perp \eta \|_{l^2(K)}^2 \lesssim (p_K^+)^8 \Psi_{p_K^+,s_K^+-1} (h_K^2)^{2s_K} \| D_\perp \|_{l^2(K)}^2 \lesssim \left( \frac{p_K}{p_K^+} \right)^8 \Psi_{p_K^+,s_K^+-1} (d_K^e)^{2b_e} \| u \|^2_{N_{s_K^+-1}(K)}. \]

which yields (7.22).

For (7.23), we proceed along the same lines and apply (7.19), (6.13) (with $|\alpha^\perp| = 2$ and $\alpha^\parallel = 0$), and (7.4). We find that
\[ (h_K^2)^2 \| D^2_\perp \eta \|_{l^2(K)}^2 \lesssim \left( \frac{p_K}{p_K^+} \right)^8 \Psi_{p_K^+,s_K^+-1} (h_K^2)^{2s_K} \| D^2_\perp \|_{l^2(K)}^2 \lesssim \left( \frac{p_K}{p_K^+} \right)^8 \Psi_{p_K^+,s_K^+-1} (d_K^e)^{2b_e} \| u \|^2_{N_{s_K^+-1}(K)}. \]
which finishes the proof. □

We are now ready to bound $\mathcal{T}_{\mathcal{U}^t_{\mathcal{E}}} [\eta]$.

**Proposition 7.5.** Let $u \in B_{-1-b}(\mathcal{U}^t_{\mathcal{E}})$ as in (7.12), (7.14). Then, there exist $b, C > 0$ such that, for $t$ sufficiently large, there holds $\mathcal{T}_{\mathcal{U}^t_{\mathcal{E}}} [\eta] \leq C \exp(-2b t)$. 

**Proof.** In view of Lemma 7.4, and using the definition of $\mathcal{U}^t_{\mathcal{E}}$, the inequalities in (7.4), the degree distributions in (7.8), and the analytic regularity (7.14), we conclude that $\mathcal{T}_{\mathcal{U}^t_{\mathcal{E}}} [\eta] \lesssim \mathbf{p}^\alpha_{\max}(S_1 + S_2)$, where the sums $S_1$ and $S_2$ are given by

$$S_1 = \sum_{j=2}^{\ell+1} \sum_{i=2}^{\ell} \Psi_{j-1,s}^i \gamma^{2(t+1-i)b_e C^2 s} \Gamma(s_j + 3)^2,$$

$$S_2 = \sum_{j=2}^{\ell} \sum_{i=2}^{\ell} \Psi_{j-1,s}^i \gamma^{2(t+1-i)b_e C^2 s} \Gamma(s_j + 4)^2.$$

The terms in the first sum $S_1$ are independent of the inner index $i$. Hence, by interpolation to real parameters $s_j^\alpha \in [3, p_j^\alpha]$ as in [11, Lemma 5.8], by applying [11, Lemma 5.12], and after possibly adjusting constants, we conclude $S_1 \leq \exp(-2b (\ell + 1)) \lesssim \exp(-2b \ell)$. The second sum $S_2$ can be estimated in exactly the same manner as the sum $S_1$ in the proof of [11, Proposition 5.17], and we obtain $S_2 \lesssim \exp(-2b \ell)$. Adjusting the constants to absorb the algebraic factor $\mathbf{p}^\alpha_{\max}$ yields the assertion. □

### 7.3.2. Exponential convergence of $\mathcal{T}_{\mathcal{U}^t_{\mathcal{E}}}$. In this subsection, we bound the terms $\mathcal{T}_{\mathcal{U}^t_{\mathcal{E}}}$ in (7.17), and first establish the following bounds for $\eta^L$, by using the properties (5.9) of the quasi-interpolation operator $\mathcal{Z}^t_{\mathcal{E}}$ for $\mathcal{R} = K^\perp$.

**Lemma 7.6.** Let $K = K^\perp \times K^\parallel_j$, $j \geq 2$, be an element in the terminal layer $\mathcal{Z}^t_{\mathcal{E}}$ of the form (7.7). For $s = 0, 1$, there holds

$$\left( \mathbf{h}_K^\parallel \right)^2 (s-1) \| \mathbf{D}^\alpha_{\perp} \eta^L \|_{L^2(K)}^2 \lesssim \sigma^{2 \min\{b_e, b_h\} \ell} |u|_{N_2 \perp, \perp}^2, \quad |\alpha^+| = s, \quad (7.24)$$

and

$$\left( \mathbf{h}_K^\parallel \right)^2 (s-1) \| \mathbf{D}^\alpha \eta^L \|_{L^2(K)}^2 \lesssim \sigma^{2 \min\{b_e, b_h\} \ell} |u|_{N_2 \perp}^2, \quad |\alpha^+| = s. \quad (7.25)$$

**Proof.** To show (7.24), we apply (5.9), to get

$$\left( \mathbf{h}_K^\parallel \right)^2 (s-1) \| \mathbf{D}^\alpha_{\perp} \eta^L \|_{L^2(K)}^2 \lesssim \left( \mathbf{h}_K^\parallel \right)^{2s-2} (h_K^\parallel)^{4-2s-2(1-b_e)} \sum_{|\alpha^+| = 2} \| u^{1-b_e} \mathbf{D}^\alpha_{\perp} \|_{L^2(K)}^2, \quad |\alpha^+| = s.$$

The application of the equivalences (7.4) implies that

$$\sum_{|\alpha^+| = 2} \| u^{1-b_e} \mathbf{D}^\alpha_{\perp} \|_{L^2(K)}^2 \lesssim (h_K^\parallel)^{-2(1-b_e)} \| u^{1-b_e} \mathbf{D}^\alpha_{\perp} \|_{L^2(K)}^2 \lesssim (h_K^\parallel)^{2b_e-2b_h} |u|_{N_2 \perp}^2.$$

Thus, combining these estimates and expressing the mesh sizes in terms of $\sigma$, cp. (7.5), (7.7), we see that, for $|\alpha^+| = s$,

$$\left( \mathbf{h}_K^\parallel \right)^2 (s-1) \| \mathbf{D}^\alpha_{\perp} \eta^L \|_{L^2(K)}^2 \lesssim (h_K^\parallel)^{2s-2} (h_K^\parallel)^{2s-2-2b_h} |u|_{N_2 \perp}^2 \lesssim \sigma^{(e+1-j)(2s-2-2b_e+2b_h)} |u|_{N_2 \perp}^2 \lesssim \sigma^{2b_e(e+1-j)+2b_e(j-1)} \sigma^{2(1-s)+2(s-1)} |u|_{N_2 \perp}^2 \lesssim \sigma^{2 \min\{b_e, b_h\} \ell} |u|_{N_2 \perp}^2.$$

To prove (7.25), we proceed similarly and obtain
\[
(h_K^2)^{(s-1)}\|D_{\perp}^s u\|_{L^2(K)}^2 \lesssim (h_K^2)^{(s-2)}(h_K^2)^{4-2(1-b_e)} \sum_{|\alpha|=2} \|r_e^{1-b_e} D_{\perp}^\alpha D_{\parallel} u\|_{L^2(K)}^2
\]
\[
\lesssim (h_K^2)^{-2(2-b_e)}(h_K^2)^{4-2(1-b_e)} \sum_{|\alpha|=2} \|r_e^{1-b_e} r_e^{1-b_e} D_{\perp}^\alpha D_{\parallel} u\|_{L^2(K)}^2
\]
\[
\lesssim \sigma^2(\ell+1-j)(-2-2b_e+2b_e)\sigma^2(1+b_e)\|u\|_{N_{-2}^{s+b_e}(K)}^2
\]
\[
\lesssim \sigma^2\min\{b_e, b_e\}\|u\|^2_{N_{-2}^{s+b_e}(K)}.
\]
This completes the proof. \(\square\)

As a consequence of the preceding lemma, we have the following approximation bound in perpendicular direction.

**Proposition 7.7.** Let \( u \in \tilde{N}_{s-1-b}^1(\tilde{O}_{ce}) \) as defined in (7.12). Then there holds \( \Upsilon_{\tilde{K}_{ce}}[\eta^\parallel] \leq C \exp(-2b\ell) \), for constants \( C, b > 0 \) independent of \( \ell \).

**Proof.** From Lemma 7.6 we find that, for \( K \in \tilde{K}_e \),
\[
(h_K^2)^{-2}\|\eta^\parallel\|_{L^2(K)}^2 + \|D_{\perp}^\parallel \eta^\parallel\|_{L^2(K)}^2 + \|D_{\parallel}^\parallel \eta^\parallel\|_{L^2(K)}^2 + (h_K^2)^2 \|D_{\parallel}^\parallel \eta^\parallel\|_{L^2(K)}^2
\]
\[
\lesssim \sigma^2\min\{b_e, b_e\}\|u\|^2_{N_{-2}^{s+b_e}(K)}.
\]
The assertion now follows by summing this estimate over all elements \( K \in \tilde{K}_e \), and by suitably adjusting constants. \(\square\)

Moreover, for the approximation error \( \eta^\parallel \) in parallel direction to edge \( e \), a similar estimate holds.

**Proposition 7.8.** Let \( u \in B_{s-1-b}(\tilde{O}_{ce}) \) as in (7.12), (7.14). Then, for \( \ell \) sufficiently large, there holds \( \Upsilon_{\tilde{K}_{ce}}[\eta^\parallel] \leq C \exp(-2b\ell) \), for constants \( b, C > 0 \) which are independent of \( \ell \geq 1 \).

**Proof.** We note that, by (7.14), (7.13), the functions \( u \) and \( D_{\perp} u \) satisfy, respectively,
\[
\|r_e^{1-b_e+\alpha} D_{\perp}^\alpha u\|_{L^2(\tilde{O}_{ce})} \leq C^{\alpha_1+1} \Gamma(\alpha_1+2), \quad \alpha_1 \geq 2,
\]
\[
\|r_e^{1-b_e+\alpha} D_{\perp}^\alpha D_{\parallel} u\|_{L^2(\tilde{O}_{ce})} \leq C^{\alpha_2+2} \Gamma(\alpha_2+2), \quad \alpha_2 \geq 2.
\]
In view of (7.5), (7.7), these properties correspond to the one-dimensional analytic regularity assumptions (6.8) and (6.12), respectively. Moreover, due to (7.8), the polynomial degrees \( p_K^\parallel \) are \( s \)-linearly increasing away from the corner \( e \). Hence, Proposition 6.2 respectively Proposition 6.3, and the tensor product structure of the elements yield
\[
\sum_{K \in \tilde{K}_e} \left( (h_K^2)^{-2}\|\eta^\parallel\|_{L^2(K)}^2 + \|D_{\perp}^\parallel \eta^\parallel\|_{L^2(K)}^2 + (h_K^2)^2 \|D_{\parallel}^\parallel \eta^\parallel\|_{L^2(K)}^2 \right) \lesssim \exp(-2b\ell),
\]
respectively, \( \sum_{K \in \tilde{K}_e} \|D_{\perp} \eta^\parallel\|_{L^2(K)}^2 \lesssim \exp(-2b\ell) \). This completes the proof. \(\square\)

Finally, we bound the term in \( \Upsilon_{\tilde{K}_{ce}}[\eta^\parallel] \).

**Proposition 7.9.** Let \( u \) be in \( \tilde{N}_{s-1-b}^1(\tilde{O}_{ce}) \) as defined in (7.12).

1. For \( K \in \tilde{K}_e \), there holds:
\[
\Upsilon_{\tilde{K}_{ce}}[\eta^\parallel] \lesssim (h_K^2)^{2b_e}(h_K^2)^{2b_e-2b_e} \|r_e^{1-b_e} D_{\perp}^\parallel D_{\parallel} u\|_{L^2(K)}^2.
\]

2. Moreover,
\[
\Upsilon_{\tilde{K}_{ce}}[\eta^\parallel] \leq C \exp(-2b\ell),
\]
with constants \( b, C > 0 \) independent of \( \ell \).
Proof. To show (7.26), we note that, by Hölder’s inequality and due to the fact that $b_e, b_e \in (0, 1)$,
\[
\sum_{|\alpha|=2} \|D_\perp^{\alpha+} \eta\|^2_{L^2(K)} \lesssim \| \rho^{1-b_e} e^{\rho^{1-b_e}} \|_{L^2(K)} \sum_{|\alpha|=2} \| r_e^{-1-b_e} \rho^{1-b_e} \|_{L^2(K)} \sum_{|\alpha|=2} \| r_e^{-1-b_e} \rho^{1-b_e} \|_{L^2(K)} \lesssim \| r_e^{-1-b_e} \rho^{1-b_e} \|_{L^2(K)} \lesssim \| r_e^{-1-b_e} \rho^{1-b_e} \|_{L^2(K)}.
\]
Then, employing (7.5) in direction parallel to $e$ yields that we have $\| h_e h^{-b_e} u \|_{L^2(K)} \approx (h_e K)^{2 b_e - 2b_e} \| r_e^{-1-b_e} \|_{L^2(K)}$. Since $|K| \approx h_e^3 (h_e K)^2$, we further have $\| r_e^{-1-b_e} \|_{L^2(K)} \lesssim |K|(h_e K)^{2 b_e - 2}$. Furthermore, for $|\alpha|=2$, noting that $D_\perp^{\alpha+} \eta = D_\perp^{\alpha+} \eta K^{-\frac{1}{2}}(D_\perp^{\alpha+} I_1^+ u) = D_\perp^{\alpha+} u$ (since $I_1^+ u \in L^1(K)$) implies (7.26).

To prove the bound (7.27), we refer to (7.26), (7.5), and (7.7). This results in
\[
T_{c,2}^K[u]| \lesssim \sigma^{2 b_e (\ell+1-j)} |u|^2_{\hat{N}_{z-1-b}(K)} = \sigma^{2 b_e (\ell+1-j)+2b_e(j-1)} |u|^2_{\hat{N}_{z-1-b}(K)} \lesssim \sigma^{2 \min(b_e, b_e) \ell} |u|^2_{\hat{N}_{z-1-b}(K)}.
\]
Summing this last bound over all elements $K \in \widehat{\mathcal{T}}^e$ yields the assertion. \hfill \Box

7.3.3. Conclusion of proof of (7.17). The proof of the exponential convergence bound (7.17) on the $hp$-dG interpolation error $\eta$ on $\widehat{O}_{ee}$ in Theorem 7.1 follows now straightforwardly by estimating the terms on the left-hand side of (7.17) using the above results.

The proof of exponential convergence (7.17) on $\widehat{D}_{ee}$ and on $\widehat{D}_{ee}$ claimed in Theorem 7.1 follows from the bound in the corner-edge patch $\widehat{D}_{ee}$ upon noticing (7.10), (7.11).

7.4. Exponential convergence estimates in elements at Dirichlet edges. Next, we consider the case where $e \in E_D$ is a Dirichlet edge, i.e., $e \in E_D$, and establish the analog of Theorem 7.1. According to (2.11) and [3], the solution regularity is characterized by the homogeneous corner-edge seminorms
\[
|u|^2_{M^{\alpha+}_{b-\beta}([\widehat{O}_{ee}])} = \sum_{|\alpha|=k} \| r_{b-\beta}^{1-b_e} \rho^{1-b_e} \|_{L^2([\widehat{O}_{ee}])} \lesssim \| D_\perp^{\alpha+} u \|_{L^2([\widehat{O}_{ee}])}, \quad k > k_\beta.
\]
While exponential convergence for solutions with regularity in this family of spaces was already shown in [11], we present an alternative argument, based on the preceding analysis of the Neumann case. We say a function $u \in H^1([\widehat{O}_{ee}])$ belongs to $A_{b-\beta}([\widehat{O}_{ee}])$ if $u \in \tilde{M}^{\ell}_{b-\beta}([\widehat{O}_{ee}])$, for $k > k_\beta$, and there is a constant $d_u > 0$ such that
\[
|u|_{\tilde{M}^{\ell}_{b-\beta}([\widehat{O}_{ee}])} \leq d_u^{k+1} k!, \quad \forall k > k_\beta.
\]
Corollary 7.10. Let $e \in E_D$ be a Dirichlet edge. Let $u \in A_{b-\beta}([\widehat{O}_{ee}])$ as in (7.28), (7.29), and let $\Pi_K$ be the elemental approximation operators chosen in accordance with Section 5.1. Then for $\eta$, $\eta^\perp$, $\eta^\parallel$ as in (5.15), (5.16), and for $\ell$ sufficiently large, there holds
\[
T_{D_{ee}}[\eta^\perp] + T_{\tilde{D}_{ee}}[\eta^\parallel] + T_{\tilde{D}_{ee}}[\eta^\parallel] + T_{\tilde{D}_{ee}}[\eta^\parallel] + T_{\tilde{D}_{ee}}[\eta^\parallel] \leq C \exp(-2b\ell),
\]
with constants $b, C > 0$ independent of $\ell$.

In addition, there holds
\[
T_{\tilde{D}_{ee}}[\eta^\perp] + T_{\tilde{D}_{ee}}[\eta^\parallel] \leq C \exp(-2b\ell),
\]
with constants $b, C > 0$ independent of $\ell$.

Proof. For every $k \geq 0$, there holds $|u|_{\tilde{M}^{\ell}_{b-\beta}([\widehat{O}_{ee}])} \leq |u|_{\tilde{M}^{\ell}_{b-\beta}([\widehat{O}_{ee}])}$. Hence, $u \in A_{b-\beta}([\widehat{O}_{ee}])$ implies $u \in B_{b-\beta}([\widehat{O}_{ee}])$, and the bound (7.30) follows from Theorem 7.1.
To bound (7.31), let $K$ be in $\hat{\mathcal{T}}^e_{\ell}$. Then, by (5.9), the definition of the corner-edge semi-norm (7.28), and the properties (7.5), we find that
\[
(h^2_K)^{-1}||\eta||^2_{L^2(K)} \lesssim (h^2_K)^{2b_e}(h^2_K)^{2(b_e-b_v)}||\eta||_{H^1(\mathcal{K})}^2 \lesssim (h^2_K)^{3b_e}(h^2_K)^{2(b_e-b_v)}|u|^2_{M^2_{1-k}(K)}.
\]
In direction parallel to edge $e$, we proceed similarly: The stability of the $L^2$-projection and equations (7.28), (7.5), yield
\[
(h^2_K)^{-1}||\eta||^2_{L^2(K)} \lesssim (h^2_K)^{-1}||u||^2_{L^2(K)} \lesssim (h^2_K)^{2b_e}(h^2_K)^{2(b_e-b_v)}|u|^2_{M^2_{1-k}(K)}.
\]
Therefore, expressing the mesh sizes in term of $\sigma$, cp. (7.5), implies
\[
(h^2_K)^{-1}||\eta||^2_{L^2(K)} + ||\eta||^2_{L^2(K)} \lesssim \sigma^{2b_e}(\sigma^{2(1-j)}(b_e-b_v)|u|^2_{M^2_{1-k}(K)} \lesssim \sigma^{2\min(b_v,b_e)}|u|^2_{M^2_{1-k}(K)}.
\]
Summing the above bound over all elements in $\hat{\mathcal{T}}^e_{\ell}$ implies the asserted exponential convergence bound.}

\[7.5. \textbf{Exponential convergence at corner elements.}\] To conclude the proof of Theorem 5.6 it remains to show exponential convergence in elements $K_e \in \hat{\mathcal{T}}^e_{\ell}$ which abut at a corner $e \in \mathcal{C}$ of $\Omega$ so that $K_e \cap e \neq \emptyset$. Such elements $K_e$ are shape-regular and axiparallel, with diameter $h_e = \mathcal{O}(\sigma^e)$. We are left to bound the term $T_{K_e}^{b_e}[\eta]$ defined in (5.25). On $K_e$, we use the quasi-interpolant $I_1$ defined in (5.6) for $\mathcal{R} = K_e$. Then
\[
\eta|_{K_e} = u|_{K_e} - I_1(u)|_{K_e}.
\]
The quasi-interpolant $I_1$ is well-defined under the (minimal) regularity $u \in W^{1,1}(K_e)$. Furthermore, by (5.8) there holds that $||\eta||_{L^2(K_e)} \lesssim h_e||\nabla \eta||_{L^2(K_e)}$ and $||\nabla \eta||_{L^2(K_e)} = ||\nabla u - I_0 \nabla u||_{L^2(K_e)}$. We conclude
\[
T_{K_e}^{b_e}[\eta] \lesssim ||\nabla u - I_0 \nabla u||^2_{L^2(K_e)} + h_e^{-1}||u||^2_{W^{2,1}(K_e)}.
\]
To bound the first term, applying standard approximations properties for $I_0$ would imply a bound of order $\mathcal{O}(h_e)$ provided $u \in H^2(K_e)$, the weaker regularity $u \in N^2_{\mathcal{R}}(K_e; \emptyset)$ suffices to obtain a (slightly weaker, yet still exponentially convergent) bound, due to the embedding $N^2_{\mathcal{R}}(K_e; \emptyset) \subset H^1(K_e)$ being compact. The next two lemmas provide an exponential bound on the first term in (7.33).

\[\textbf{Lemma 7.11.}\] For corner weight parameters $b_e \in (0,1/2)$, and weight edge parameters $b_v \in (0,1)$, for $e \in \mathcal{E}_e \subset \mathcal{E}_N$, $e \in \mathcal{C}$, we have the compact embeddings
\[
N^2_{\mathcal{R}}(K_e; \emptyset) \subset L^2(K_e), \quad N^2_{\mathcal{R}}(K_e; \emptyset) \subset H^1(K_e).
\]

\[\textbf{Proof.}\] We note that, in the $N^2_{\mathcal{R}}$-spaces above, all edges $e \in \mathcal{E}_e$ are Neumann edges (although all that follows will hold verbatim if only some $e \in \mathcal{E}_e$ belong to $\mathcal{E}_N$). We write, for simplicity, $N^2_{\mathcal{R}}(K_e)$ in place of $N^2_{\mathcal{R}}(K_e; \emptyset)$. The key observation of the proof is the equivalence $N^2_{\mathcal{R}}(K_e) \simeq H^{2,2}_{\beta_{m,2}}(K_e)$ proved in [8, Section 2] for the indicated range of weight exponents $\beta_m \in (0,1/2)$ and $\beta_{ij} \in (0,1)$ (cp. (2.10) and Remark 2.2).

Then, [8, Theorem 3.8] implies that $H^{1+\theta}(K_e) \supset H^{2,2}_{\beta_{m,2}}(K_e) \simeq N^2_{\mathcal{R}}(K_e)$, with continuous embedding, provided that $\theta := 1 - \max{\beta_m, \beta_{ij}} > \epsilon$, for sufficiently small $\epsilon > 0$. Using that $\beta_{ij} = \beta_e + 2$ and $\beta_m = \beta_e + 2$ (cp. Remark 2.2), we obtain $\theta \in (0,1)$ if and only if $0 < b_e < 1$ and $0 < b_v < 1/2$, cp. (2.10), which is the asserted range of corner and edge weight exponents. The compactness of the second embedding in (7.34) now follows from the fact that it is a composition of the continuous embedding $N^2_{\mathcal{R}}(K_e) \subset H^{1+\theta}(K_e)$ and the compact (by Rellich's Theorem) injection $H^{1+\theta}(K_e) \subset H^1(K_e)$ for $\theta > 0$. The compactness of the first embedding in (7.34) follows analogously. \[\square\]
Lemma 7.12. Let $u \in \mathcal{N}_h^2(K;\mathcal{C},\mathcal{E}_D)$, with edge weights $\beta_e \in (-2,-1)$ and corner weights $\beta_c \in (-3/2,-1)$. Then for the quasi-interpolant $I_4$ for $\kappa = K$ in (5.6), there exists $C > 0$ independent of $h_e \in (0,1]$ and of $u$ such that $\|\nabla (u - I_4 u)\|_{L^2(K_e)} = \|\nabla u - \Pi_0 \nabla u\|_{L^2(K_e)} \leq C h_e^{1-\beta_c} \|u\|_{\mathcal{N}_h^2(K;\mathcal{C},\mathcal{E}_D)}$.

Proof. We observe that $u \in \mathcal{N}_h^2(K;\mathcal{C},\mathcal{E}_D)$ implies that $\nabla u \in \mathcal{N}_h^2(K;\mathcal{C},\mathcal{E}_D)^3$. We denote $v = \nabla u \in \mathcal{N}_h^2(K;\mathcal{C},\mathcal{E}_D)^3$. Observe that $\Pi_0(v)$ is the (componentwise) average of $v$ over $K_e$. From the compactness of the embedding $\mathcal{N}_h^2(K;\mathcal{C},\mathcal{E}_D)^3 \subset L^2(K_e)^3$ in Lemma 7.11, we proceed along the lines of [13, Section A.2.4] and use appropriate scaling (in particular, recalling that $-2 < \beta_c < -1$ implies that, for $k = 1$ in the sixth term of (2.11), the inhomogeneous weight exponent $\beta_c + |\alpha - 1| < 0$) to conclude that there exists a constant $C > 0$ independent of $v$ such that $\|v - \Pi_0(v)\|_{L^2(K_e)} \leq C h_e^{-1-\beta_c} \|v\|_{\mathcal{N}_h^2(K_e)}$. Referring to (2.10) completes the proof. \hfill \Box

It remains to bound the term $h_e^{-1} \|u\|_{W^{2,1}(K_e)}$ in (7.33).

Lemma 7.13. Let $u \in \mathcal{N}_h^2(K;\mathcal{C},\mathcal{E}_D)$, with some $\beta_e \in (-2,-1)$, and with some $\beta_c \in (-3/2,-1)$, and for $K_e \in \mathcal{T}_h$ with $\bar{K}_c \cap e \neq \emptyset$, and $\bar{K}_c \cap e \neq \emptyset$ for $e \subset \bar{T}_e$, for some $e \in \mathcal{E}_N$. Then, for any $0 < h_e = \text{diam}(K_e) \leq 1$, there holds

$$\|u\|_{W^{2,1}(K_e)} \lesssim h_e^{1/2} \|u\|_{\mathcal{N}_h^2(K;\mathcal{C},\mathcal{E}_D)}.$$  \hfill (7.35)

Here, $h_e = -1 - \beta_c \in (0,1/2)$ is as in (2.10).

Proof. We may assume that $K_e \cap \omega_e = \emptyset$. There holds

$$\|u\|_{W^{2,1}(K_e)} = \sum_{|\alpha| = 2} \|D^\alpha u\|_{L^1(K_e)} = \sum_{|\alpha| = 2} \|D^\alpha u\|_{L^1(K_e \cap \omega_e)} + \sum_{|\alpha| = 2} \|D^\alpha u\|_{L^1(K_e \setminus \omega_e)}$$

$$\leq 2 \left( \sum_{|\alpha| = 2} \|r_e^{1-h_c - |\alpha|} \|_{L^2(K_e \cap \omega_e)} \|e^{-1-|\alpha|} E_{\alpha} \|_{L^2(K_e \cap \omega_e)} + \sum_{|\alpha| = 2} \|r_e^{1-h_c - |\alpha|} \|_{L^2(K_e \cap \omega_e)} \|e^{-1-|\alpha|} E_{\alpha} \|_{L^2(K_e \cap \omega_e)} \right).$$

We note that, for $0 \leq |\alpha| \leq 2$, there holds

$$\|r_e^{1-h_c - |\alpha|} \|_{L^2(K_e \cap \omega_e)} \lesssim h_e^{1/2},$$

and similarly,

$$\|r_e^{1-h_c - |\alpha|} \|_{L^2(K_e \setminus \omega_e)} \lesssim h_e^{1/2}.$$  \hfill (7.36)

We arrive at

$$\sum_{|\alpha| = 2} \|D^\alpha u\|_{L^1(K_e)} \lesssim \|u\|_{\mathcal{N}_h^2(K;\mathcal{C},\mathcal{E}_D)}$$

which completes the proof. \hfill \Box

Inserting the estimates in the previous lemmas into (7.33), we arrive at the following exponential convergence result in corner elements.

Proposition 7.14. Let $u \in \mathcal{N}^{1-\kappa}_h(\mathcal{T}^e_{\text{neu}})$, with $b$ as in Remark 2.4. Then, there exist constants $b, C > 0$ such that $\|u\|_{\mathcal{N}^{1-\kappa}_h(\mathcal{T}^e_{\text{neu}})} \leq C \exp(-2b\ell) \|u\|_{\mathcal{N}^{1-\kappa}_h(\mathcal{T}^e_{\text{neu}})}$.

7.6. Proof of Theorem 5.6. The exponential convergence of $hp$-dGFM, Theorem 5.6, follows now immediately from the quasi-optimality results, Theorem 5.5, and from the fact that, by our analysis in Section 7, all terms on the right-hand side of the estimate (5.28) converge exponentially with respect to the number of mesh layers $\ell$. Furthermore, for the number of degrees of freedom in either of the $hp$-dG spaces in (3.10) and (3.11) there holds $N \approx \ell^d + O(\ell^d)$, which yields the desired estimate (5.32).

Remark 7.15. We note that Theorem 5.6 remains true in the pure Neumann case. Indeed, the $hp$-approximation analysis on geometric meshes presented in this work as applied to the $hp$-dGFM (4.2) with $F_D(M) = \emptyset$ and based on the $hp$-space $V(M, \Phi, p)/R$ leads to the bound (5.32) as well. This simply follows from the fact that all the interpolants in our error analysis reproduce constant functions.
